The internal individual approach is committed to a subjective claim for recognition and strives for truth, dependability and sincerity. Interests and convictions are frequently looked at from a phenomenological point of view and interpreted hermeneutically (quadrant 1). In this quadrant, the empirically proven efficiency of self-regulation is not the central issue. Rather, the question is how relevant a concept is for an individual teacher or pupil in terms of their subjective view of the world and how to relate it to their own actions.

In the outer collective quadrant a complex all-encompassing system is the primary reality. In this systemic view the overall system defines the many functions for its separate components. Zierer (2008) calls this "the requirement to fit in functionally" meaning that the single parts "must be woven into the fabric of the overall system" (p. 576). From this perspective it should be possible to prove through objective and empirical evidence that ongoing support of self-regulation leads to the smooth transition of those in learning into the overall economic structure of their country.

Wilber (2001) defines the inner collective quadrant as situated in a cultural context. An inter-subjective claim for recognition is negotiated among two or more individuals. Justice and mutual understanding are central considerations which do not necessarily lead to an objective linking of systems. Social and cultural behaviour is acted out in rituals and procedures which are recognized by the participants to be right and just. For self-regulation to flourish in this quadrant, it is important that those actively involved are in agreement about the role that self-determination should play in the learning process and how it should be adapted into the everyday reality of the school.

Table 1: Overview of the quadrants in Wilber’s integral theory.

	Inside	Outside
Individual	**I Intentional** Subjective demand for recognition (Genuineness) *What does self-regulation mean for my own learning?*	**II Conduct** Objective demand for recognition (Truth) *How can self-regulation be supported effectively?*
Collective	**III Cultural** The inter-subjective claim for recognition (Justice / Cultural fitting in) *How can self-regulation be implemented into day to day school life?*	**IV Intentional** The inter-objective claim for recognition (Functional fitting in) *Are there benefits for the overall economy if self-regulation is encouraged?*

Self-regulation

Self-regulation is the ability to adapt one’s actions to the achievement of medium-term and long-term goals while managing to handle adversity appropriately whether it be from the outside or from within. It is based on the interaction of cognitive, metacognitive and motivational-emotional resources (Artelt, Demmrich & Baumert, 2001). From the integral viewpoint quadrants 1 and 2 (Wilber, 2001) cover those training programmes which consider the thoughts, purposes and the intentions (quadrant 1) as well as the measurable behaviour (quadrant 2) of the individual. Collective perspectives are not explored. The great majority of empirical evaluation studies explore the measures used to support self-regulated learning among pupils in the lower grades of secondary school (“Sekundarstufe 1”). In terms of methodology and validity they can be assigned to quadrant 2 (Zierer, 2008).

The Cologne action model (“Kölner Handlungskreismodell”, Aschermann & Armbrüster, 2011) describes self-regulation as a circular process in which the behavioural steps associated with cognitive and motivational-emotional processes are anchored. It is founded in Heckhausen’s model of the regulation of action (Heckhausen & Heckhausen, 2008). Heckhausen defines four cognitive phases (setting a goal, planning, implementation, evaluation). Schmitz and Schmidt (2007) as well as Zimmerman (2000) proposed and evaluated similar self-regulation models. These fundamental models of self-determined learning emphasize the importance of emotions for the learning process but do not explicitly root them there. In our model the scope has been widened to include more detailed specifics on the interaction between the processes of regulation and cognitive processes necessary for a successful learning activity. The effectiveness of further training to encourage self-regulation was demonstrated by an empirical evaluation study in a schools context (Armbrüster, 2013).

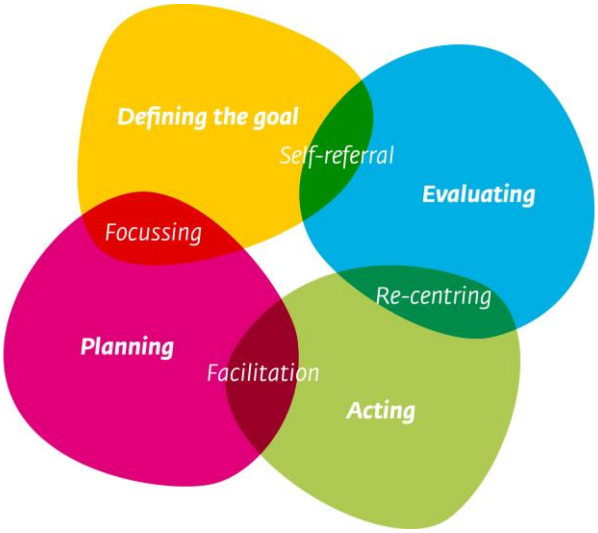

Fig. 1: Cologne action model (Aschermann & Armbrüster, 2011)

Cognitive Processes

If learning is to be successful, it is important to have a clear and well-defined **objective**. The individuals have to be in a position to take their own decisions and to deal with a subject matter with real enthusiasm. **Planning** involves the definition of partial goals, setting priorities, anticipating possible obstacles and the consideration of alternatives. The **task in hand** demands self-confidence and the ability to apply oneself even when more attractive options or seemingly more urgent activities lure because progress is slow. **Evaluation** includes recording the results of the tasks set, as well as verification whether my own objectives have been achieved. Significantly, this calls for a meta-perspective which allows observing my own learning process in order to achieve realistic self-assessment.

Regulating Processes

In-between each step characteristic mood swings occur which determine the smooth flow of events. The ability to influence one’s own emotions is significant for the successful outcome of a learning process. If an evaluation is to be carried out, it is crucial to have the ability to cope with failure or to be able to reassess the overall situation after detailed analysis.

When a new task is set, the mood should ideally be one of enthusiasm and optimism from the outset. When the planning stage arrives, feelings in general turn more sober, especially when obstacles become apparent (**focussing**). Starting and persevering are easier when the general mood is that of confidence (**facilitation**). During evaluation there is stronger attention to detail and the mood gets more serious (**re-centring**). The conclusions generated by evaluation are then transferred into the context of one’s own experience. The subsequent change of direction towards a new goal once again demands emotional energizing (**self-referral**).

Although there are relatively stable differences in the personal priorities when it comes to individual cognitive and regulating phases, we contend that all components can be changed through a learning experience.

Objectives of the Study

This study in support of self-regulation in the lower grades of secondary school examines the question how a collaboration group and a training support group made up of teachers differ in the implementation of their further training during their maths lessons. The study also looks into the differences of how the two groups reflect both personally and socially on the concept of self-regulation during school lessons. The main emphasis is on the analysis of the teacher's individual planning for lessons and their views on the importance of self-regulation during learning. In addition, the project measured the learning progress of the pupils. The data is not included in this paper as it is due to be published shortly (Klenzan, in press).

Method

This indirect intervention study was undertaken as a project in collaboration between a university and five secondary schools ("Gymnasium"). Ten classes took part and the teachers were assigned to one of three conditions: a collaboration group (N = 6) or a further training group (N = 4). The teachers in the collaboration group all worked at the same school, the teachers of the further training group worked on two different schools nearby. The teachers in the collaboration group and the further training group received identical training on the subject of self-regulation. The teachers in the further training group applied their newly acquired training skills individually to the lessons they were teaching. The collaboration group on the other hand shared these skills with their maths teaching colleagues and applied them to classes (cf. later). These distinctions were put in place deliberately in order to distinguish the effects shown through further training and teaching in collaboration. The teachers implemented the further training that they received into their maths lessons for a total number of 12 weeks. The study is based on a pre-post design. The treatment effects were collated using a post-test shortly after intervention took place. A later survey recorded the longer-term effects. Data readings were taken three times and always based on evaluation-related variables. The period during which the study was undertaken lasted for one school year. The actual evaluation period lasted just over half a year.

The Training Syllabus

The teachers in the further training and collaboration groups participated in two training sessions on the subject of self-regulation lasting half a day each (cf. Table 2). The first training session introduced the teachers to the subject of self-regulation. The theoretical background used was the Cologne action model (see above).

The main objective of the first day was to introduce the teachers to the concept of self-regulation as a basis for motivated learning in school. During the "mental journey" - phase, the teachers were mentally guided through a complex project (organizing an event). Their task was to pay attention to their own reactions, feelings and ideas during this mental journey. In the ensuing discussion they compared their own experiences with those of the learning tasks they had set their pupils only to discover that they were undergoing a similar learning experience to that of their pupils. The Cologne action model enabled the teachers to talk about the difficulties of motivating pupils without referring solely to the personality traits of the pupils.

Table 2: Day 1 syllabus.

DAY 1 **Phase of the training**	**Specification**
Introduction	First acquaintance, importance of self-regulation in learning contexts
Keynote Speech	Idea and benefit of self-regulation, special relevance for the mathematics instruction
Group discussion	Specification of the phases, creating a school reference
Mental journey	Self-regulation in the teachers life, clarification of functional and dysfunctional behaviour patterns
Workshops	In-depth insight in the field of self-regulation
Discussion and reflection	Questions and feedback, agenda setting for day 2

During the second training session, the teachers were given examples of how to encourage self-regulated learning in the maths lessons. The contents of the syllabus corresponded to the Cologne action model and were divided into the four units, namely defining the objective, planning, the taking of action and evaluation. Priority was given to the link between theory and the practical application in school with a particular emphasis on the practicality of the syllabus and its successful transfer to lessons.

Table 3: Day 2 syllabus.

DAY 2 **Phase of the training**	**Specification**
Introduction	Exchanging experiences and identifying central aspects the teachers wanted to work on
Defining the goal	The purpose of setting a goal is to elicit a motivating effect
Planning	Goals are manageable if split into sub-goals; planning maths lessons
Action	Invested study time and used learning strategies are significant aspects
Evaluating	Feedback is an influencing factor of causal attribution
Discussion	Questions and feedback

The training was devised specifically for the purpose of making it adaptable for teaching in class. Therefore adaptations were not only desirable but necessary and were discussed with the teachers. In a situation where self-regulated learning is encouraged it does not seem practical to make teachers follow a strict regime, as implementation very much depends on the teaching unit in hand and the makeup of the class itself. The teachers who participated were introduced to the possibilities of how to encourage self-determined learning and how to apply it within the context of their maths teaching. It was explained that these were merely suggestions to encourage self-regulated learning. Additional ideas for implementation were expressly encouraged. Three areas of special interest were formulated by the teachers during this training phase:

- How can pupils be supported to give them a realistic picture of their knowledge and competencies in order for them to prepare more independently for written tests?
- Pupils need to revise far more rigorously to attain basic mathematical skills (equations with variables, division of fractions, embedded problems)
- Cooperation in the class while working on a complex problem should be fostered

These aspects are the basis for the collaborative work between the teachers and the research group as well as being the focal point for supervision in the training group.

Shaping Transdisciplinary Cooperation

Continuous exchange between teachers: During the period of implementation, a continuous exchange between the members of the collaboration group was initiated and supervised. This discussion took place on three levels: the teachers worked together on didactic impulses for encouraging self-regulated learning. Ideas for implementation were floated and experiences were adapted accordingly. These exchanges took place within the context of personal conversations during the breaks or free time in-between lessons.

Transdisciplinary contact: To enable the transdisciplinary exchanges between teachers and researchers, regular meetings were arranged once a week. These meetings lasted about 90 - 120 minutes and took place at the school. The ideas and thoughts of teachers and researchers contributed mutually to the progress of the work. On the one hand these meetings served to clarify the next steps to be taken and allowed room for the exchange of views on the experience gained previously. On the other hand, the meetings strengthened personal contacts. Transdisciplinary perspectives and experiences were brought together and could be used for future implementation. This notion of collaboration across disciplines contradicts the “Research, Development and Diffusion paradigm” (RDD, Krainer, 2003) in which teachers are solely seen as the recipients of research findings.

Support website math-il.de: Cooperation among the group of teachers was further supported through the web platform math-il.de. Participants were able to exchange views flexibly regardless of time and place. The working group consisted of the participating number of six teachers plus university staff from the faculties of Mathematical Didactics and Educational Psychology. The platform served as an additional source for exchange and for uploading ready-made teaching materials.

It is through these impulses that changes in respect of individual approaches and convictions (quadrant 1) as well as of conduct (quadrant 2) were to be achieved. Changes in the school's circumstances (quadrant 3) were also to be documented. A change in terms of the inter-objective claim for recognition (quadrant 4) was not intended.

Observations in Class plus Interviews

During the period of intervention each teacher was observed twice in class for the purpose of recording the self-regulating components during the lesson. All observations were conducted by the same member of the university team. The central observation was how the Cologne action model was implemented in the lesson. The following observation grid to code the relevant aspects that were found in each lesson was devised exclusively for this purpose:

- Type of classroom instruction: teacher centered, working in groups, lecture, pupils working by themselves
- Activities of pupils during the lesson: the amount of time needed to complete the task, discussion of the maths problems, seeking help from the teacher or other pupils
- Possibility of independent self-regulated work in the class (amount of time, intensity)
- The introduction of self-regulation teaching aids
- Looking at how the different phases were implemented

The focus here lay specifically in the observation whether at least one of the four action phases had been implemented and how it was brought about. Further, the general presence of the action model during the lesson was recorded (visual presence and / or the explicit naming of a particular phase). The observations in class were based on fundamental criteria seen as prerequisites for self-regulated learning such as the prevailing teaching method and the perceived independence of the pupils (Hattie, 2009). In the course of three measuring periods, extensive interviews were conducted with the teachers in the collaboration and further training groups. Different members of the research group conducted the semi-structured interviews. They were recorded and subsequently transcribed. The subjects discussed during the interviews were expectations, knowledge, the changes that the teachers themselves perceived regarding their own planning and their teaching, the subjective theories about learning in school and the reactions of the pupils in view of the changes taking place during lessons. We use the method of Mayring (2010) for coding the teacher's statements. This method was chosen to deepen our knowledge of the teacher's thoughts, their feelings, meanings and their interpretation of teaching in their specific situation. The thematic analysis consisted of a two-step procedure. In the paraphrasing phase initial codes were generated by extracting interesting features from the data set. The relevant data for each feature was then given a code. Repetitions and embellishments were omitted. In the generalization phase the relevant themes emerging form the coding were extracted and named. Central topics of the pre and post interviews are summarized in table 4.

Table 4: Main topics of the semi-structured interviews

Pre interview	Post interview	Follow-up interview
– Personal ideas and reasons to participate in the project	– Applying the training materials in a classroom setting - regularity and intensity	– Do you still support self-regulated learning? – What changed?
– Individual objectives in the project	– Which aspects regarding the training were useful in your lessons?	– Continuation of teacher collaboration
– Definition of self-regulation	– Difficulties and obstacles encountered	– How intense was the practical implementation?
– Advance knowledge about self-regulation	– Solutions and alternatives	– How was the implementation structured?
– Assessment knowledge: How do you identify the self-regulation competences of your pupils?	– Prospective utilization of self-regulation in lessons – Did the project lead to cooperation with other teachers?	– Are there any reasons why training should not be undertaken?
–	– Results of the collaboration?	– What are benefits / costs of self-regulated learning?

Results

We will present the results in the order of Wilber’s Integral Modell (2001). First, we will focus on how the teachers analyzed the project from a subjective perspective (focus on quadrant 1). This is followed by a description of how the syllabus of the further training was applied during lessons by both groups as perceived by the classroom observers (focus on quadrant 2) and the type of activities developed by the collaboration group (focus on quadrant 3). Although inter-objective changes were not taken into account here, the results are mentioned for the purposes of a complete representation (quadrant 4).

Quadrant 1: How Important is Self-regulation for my Teaching / for the Apprehension of my Pupils?

The focus of the interviews was the question whether implementation of self-regulated learning had taken place and from the teacher’s point of view in what way implementation had differed in the collaboration group and the further training group. This qualitative procedure fits quadrant 1 because the individual perspective is particularly clear here. Post interviews were conducted with nine teachers, six from the collaborative group and three from the training group (one teacher could not be interviewed due to parental leave).

In table 5 the results of the post-interview are summarized. For each category derived by the qualitative interpretation method the number of teachers who made statements relating to one of the categories below and the sum of all statements are shown.

Table 5: Overview of categories extracted from post-interviews and frequency of statements.

Category	**Number of entries (teachers / statements)**	
	Collaborative group (N = 6)	Training group (N = 3)
Implementation process	5/21	2/2
Self-reflection of teachers	5/8	2/2
Learning progress for pupils	4/9	2/2
Reflection of specific phases in the Cologne action model	6/9	3/3
Collaboration	6/12	1/2
Positive impact on teaching and learning	6/7	2/1
Difficulities encountered	6/6	3/3
Developement of new maths tasks	5/6	2/4
Structure of the lessons	3/3	1/2
Future use of self-regulated learning	6/7	2/2
Costs of implementation (e.g. time, conflicts)	4/6	2/2
Website math-il.de	6/9	-/-

Eight teachers stated that they had implemented the action model either implicitly or explicitly in class. Of those eight teachers six belonged to the collaboration group while two belonged to the further training group. All eight teachers stated that they intended to continue using the action model.

The teachers of the collaborative group elaborated in detail on the process of implementation. They focused often on the learning processes of the pupils and used the action model in a differentiated manner to describe the positive changes in the lessons. Teachers of both groups reported some difficulties; these were in all interviews mostly attributed to the time the pupils needed to adjust to a new format of lessons. Teachers of the collaborative group talked more often about changes in their own perception of the learning process than the teachers in the training group. Analysis of the post-interviews shows that all six teachers in the collaboration group experienced cooperation as most satisfactory and effective. The discussions with their colleagues were very much appreciated and led to a broader understanding of learning practices. Only one teacher stated that he or she found cooperation too time-consuming. It was also stated that cooperation added to an improved feeling of social cohesion among the teaching staff und to much improved personal satisfaction in the day to day business of the school. Two teachers pointed out that the positive effects of cooperation had led to getting to know a new colleague (female teacher in the post-interview of the cooperation group: “All six colleagues cooperated at regular intervals, consulted each other, devised work sheets, developed written tests. This is something I had never experienced before, especially that all the teachers worked together.”)

The website math-il.de was not considered a practical support tool. The reason being was that personal contact and the exchange of views were felt to be more convenient and more satisfactory. The exchange of teaching materials and permanent access were mentioned positively.

Reflections on the action phases for the pupils were a frequent theme during the interviews:

> What I noticed more the second time round and that is important to me is how much we miss looking back and reflecting on the objectives, planning, acting and evaluation during the lessons. Especially in this mode we have become aware of how much the teacher is involved. Perhaps that is how it should be to ensure that the lesson can be maintained in its structure as prescribed by the curriculum. In my view it could be an advantage for many pupils if they thought more about how they could be more pro-active. (Teacher post-interview, collaboration group).

By contrasting two quotes from teachers from the collaboration group and the further training group on the subject of evaluation and objectives, the conceptual differences on teacher level become obvious:

> Teacher (male) cooperation group: How did Cologne action model help?
>
> In the beginning the pupils had to work out what they wanted to do and what their objective would be. They were also encouraged to reflect retrospectively before entering the next circle and steering towards the new goal. They had to reflect on their conclusions and decide whether they had reached their objectives. Then they had to think about how they would need to change direction if they wanted to be more successful the next time round. I liked that.
>
> Teacher (female) further training group:
>
> I found that the list was helpful for evaluation. That is something I do not normally do. They only write things down in their rulebook. However, a list which enables them to check their progress and is good for revision. I find that defining an objective is difficult as it is prescribed anyway. It is not possible to apply that in reality.

While the female teacher in the further training group acknowledges the importance of evaluation for the learning process, she perceives the objectives as prescriptive and not open to change by either her pupils or herself. In comparison, the male teacher from the collaboration group links evaluation and the definition of objectives with each other and thus describes the cyclical character of the action model as a central element.

Follow-up interviews examined whether a transfer had occurred after intervention and if so to what extent. Nine teachers agreed to participate in the follow-up. Three teachers of the collaboration group (N = 6) and one of the training group (N = 3) stated that self-regulated learning would continue to be encouraged along the lines of the action model after intervention. Teachers and pupils found the opportunity to take stock of the lesson by encouraging the pupils to evaluate (evaluation and self-referral) their own progress during lessons useful. The pupils welcomed the chance to set their own goals. Once the project had come to an end all teachers noted that the intensity of self-regulated learning had diminished.

Despite the positive feedback of the post-interviews the collaborative processes were not perpetuated after the intervention. Merely two of the five teachers in the collaboration group stated that they were still practicing some form of collaboration. The failure to continue with this type of cooperation was put down to lack of time and occasion. It was also stated on more than one occasion that without set tasks and tangible objectives collaboration among the teaching staff does not take place (female teacher in follow-up interview collaboration group: “None of the form teachers in the whole grade would cooperate if the impetus had not been given through an external project like this”).

Overall, the teachers in both groups implemented self-regulated learning during the project time and noticed mainly positive effects on the learning behavior of their pupils. Particularly the phases of goal setting and self-reflection were recognized as useful for the development of a more self-determined teaching style. The teachers considered the problems encountered as manageable.

Quadrant 2: How is the Training Syllabus Implemented in Teaching?

In addition to the subjective impressions of the implementation process, the classroom observations served as a means to get a clearer picture of what happened during lessons.

Twenty lessons were observed and coded and it should be pointed out that this sample is rather small in order to come to a general conclusion. Without doubt the observations did make an impression and complemented the teachers’ own perceptions.

The focus here lay specifically in the observation whether at least one of the four action phases had been implemented and how it was brought about. Further, the general presence of the action model during the lesson was recorded (visual presence and / or the explicit naming of a particular phase). The observations in class were based on fundamental criteria seen as prerequisites for self-regulated learning such as the prevailing teaching method and the perceived independence of the pupils (Hattie, 2009).

Type of classroom instruction: Quite a number of maths lessons were observed which were characterized by an open practice of setting tasks as well as a high proportion of active learning time. However, the dominant method of teaching in the collaboration group was from the front of the class. This may be due to the low number of lessons observed but it is very typical for teaching in secondary school in Germany. The teachers did a lot of the talking while the pupils took on a mostly receptive role while learning. This means that there are few opportunities for self-regulation. The teaching of the further training group was mostly centered on the teacher too. It too was characterized by teaching in front of class and teachers who did a lot of the talking. The pupils received substantial direction and the teachers frequently asked the pupils questions, which meant that they had little opportunity to practice self-regulated learning. There were only a few lessons which had a more open feel and a larger proportion of active learning time.

Emphasis on the self-regulation model: There was a poster of the action model displayed in almost all classrooms. It was therefore present during most classroom observations. The model itself and specific phases were mentioned regularly in the collaboration group. The indirect implementation of individual phases occurred frequently. The implementation was evident throughout in check-lists, the free choice of set tasks and in the application of teaching materials devised by the teacher. In the further training group, the action model was also displayed as a poster; individual phases were not explicitly mentioned during lessons.

In sum, there were two noticeable differences between the two groups: teachers in the collaboration group dropped far more metacommunicative hints on the action model and the current phase in which they situated the activities of their pupils than the teachers in the further training group. They also dared to deviate from the teacher centred teaching method so typical for Germany far more often and consistently, thus giving the pupils more freedom to work on the tasks set either individually or in partnership.

When comparing implementation between the two groups of teachers another difference is obvious: the teachers in the further training group were willing to include the elements for encouraging self-regulation, which they had been introduced to, in their own lessons with minimal changes. They laid the main focus on a single action phase as discussed during training. In contrast, the teachers in the collaboration group developed a more complex target. Pupils were expected to complete the action model fully and independently in the space of a double lesson.

Quadrant 3: How can we Implement Self-regulation in Class Together?

Before the project kicked off some of the teachers in the collaboration group were skeptical about the planned cooperation. They were particularly worried that processes affording cooperation would be very time consuming. During intervention an overall invigorating mood developed. The protagonists acted in harmony with each other. One of the female teachers described her experiences thus:” You tend to be more stimulated. I noticed that the whole thing was specially designed so that all of us develop this together. We were not forced to use anything that was prescribed. Nor did I have the feeling that I needed to know all the answers. I was simply able to contribute what I could, based on my current level of expertise.”

The action model was introduced into the collaboration classes in close coordination with a colleague whose teaching subject was not related but who had experience in the area of encouraging self-regulation and had also taken part in the two training sessions.

All teachers attended the weekly meetings of the project more or less without exception. Initially the meetings served to discuss the application of the training contents. Later on the discussion shifted to exchanges about the methods that had been implemented and their possible adaptations. Individual teachers developed their own teaching materials for the purpose of implementing the action model. They would make these materials available to their colleagues on math-il.de (teacher post-interview, collaboration group: ”We had to work together more closely. It was very helpful to exchange views regularly on how certain set tasks had worked out, even if it was only in passing on the corridor. We would discuss what had worked out and what had not, how perhaps to phrase questions differently or so. That was good and more intense than I had expected.”).

One teacher even had the idea to ask his pupils to select their own exercises from an assignment pool and to solve them on their own. The exercises were graded into five levels of difficulty. The work in progress from defining the objective (which exercise will I work on?) to marking was to be recorded in writing. This illustrates how standardized assignments can be developed into an individual process. In preparation of a written test one of the teachers developed a work sheet which is divided into the four cognitive self-regulating phases. On this work sheet the pupils can record what their objective for solving this written test is (defining objective) and how they plan to go ahead (planning). On the back of the work sheet the pupils are able to document how many days they spent revising for the test for the action phase. The evaluation phase is divided into three parts: (1) evaluating the individual preparation before the written test, (2) evaluation of the pupil’s own performance during the lesson following the written test and (3) evaluation after returning the test.

The test was developed in partnership by the teachers in the collaboration group. During the weekly meetings the learning objectives and the quality for measuring performance of the exercises were discussed thoroughly and in great detail. The teachers marked the tests collectively too. This was a new experience for the teachers who normally mark the tests in isolation.

In addition the teachers developed so-called “warm-up exercises” which were introduced routinely at the beginning of each maths lesson. These exercises served to support pupils in their self-assessment similar to those exercises for defining objectives. The exercises gave the pupils the opportunity to formulate their personal objectives based on their current status of knowledge. The warm-ups displayed the date of the training course, the predicted number of correct answers and real number of correct answers as well as the self-assessed level of confidence while solving the problems (level 1 = very confident to level 6 = very uncertain). This enabled pupils to follow their own learning progress. The exercises were intended for revision and for consolidating basic abilities and were therefore not very difficult. The time allowed was roughly five minutes. While considering the purpose and scope of the warm-ups, the teachers discussed at length their personal views on the importance of specific aspects of learning and pursuing mathematics. Often these discussions resulted in self-reflection. The teachers in the collaboration group used the action model as a meta-language to express their own learning process when disagreements occurred.

During the eight-week period of intervention over 30 documents were uploaded on the website math-il.de (in particular work sheets, articles, presentations, one written test). Teachers used the blog for immediate exchanges. The teachers did not use the internet platform much at the beginning. Towards the end of the intervention period this instrument was being used more often.

Teachers in the collaboration group even approached the school's management with suggestions for changes in the system. These changes were implemented in the following term. For the teachers in the collaboration group the most important objective was to have one hour of free time free of lessons in order to make it easier for them to get together and discuss.

Quadrant 4: Is Self-regulation Useful to Cope in a Knowledge Based Society?

The outer / collective perspective according to Wilber (2001) had no central part in this study. The long-term effects of improved self-regulation may only be demonstrated through education panels given a wide-ranging scope or through changes in society at large. The great commitment that the teachers showed in this study indicates that these "experts for learning" are convinced of the necessity and effectiveness of this approach and ultimately used it in their own teaching. The exceptionally intense and wide research activity in Germany on the subject of self-regulation is closely related to society's efforts to take into account individual skills and interests and including them in the learning processes in schools for the purposes of lifelong learning. We will know in a few years' time whether or not this approach has succeeded.

Discussion

The aim of this study was to show how the contents of motivational psychological further training can be applied to the teaching of mathematics in the lower school grades of a secondary school. The central theme was to encourage self-regulation according to the Cologne action model. After receiving two training sessions the members of the collaboration group went about implementation by cooperating with each other and started to make changes to their lessons in which the pupils were directed towards more intensive self-regulation. The members of the further training group applied these contents individually and with no exchange of views amongst the group.

Our data suggest differences between the two groups on a number of levels. During the discussions and behavioural observations it became clear that the members of the collaboration group had opted for a much more complex approach to impart the concept of self-regulation amongst their pupils. The teachers in this group intended to design their lessons in a way that pupils were able to complete a full cycle of set tasks by solving a more complex mathematical problem on their own within the scope of the double lesson. They recognized the importance of the connection between evaluation and the subsequent step of defining the new objective. For this purpose, they devised their own exercises and lesson routines. During meetings with the university cooperation partners, it was pointed out that completing a full cycle of tasks could present a complex challenge for pupils and that they might feel that too much is expected of them. The teachers in the collaboration group agreed with this assessment but decided that they would continue to pursue their didactically ambitious goal. They argued that they hoped the long-term effects would be beneficial because lessons would open up more and that this would fire up the pupil's enthusiasm and interest in the subject matter.

This approach was indeed shared by the members of the university on the grounds of creating a level playing field in the area of academic research and development. The interviews recorded after the implementation phase showed that the teachers in this group had a much deeper understanding of the basic psychological and mathematical didactical concepts. Their pupils had a greater understanding of the cyclicality of action phases and the importance of evaluation followed by the definition of objectives for the purposes of a successful learning experience. The teachers in the collaboration group also used the concepts, which they had acquired to describe and reflect on their own learning process. Here too we see a transfer of a complex nature.

Our study is in line with a growing number of research projects focused on the implementation of teaching strategies aimed at how to foster strategic and self-regulated learning (Gräsel, 2010; Krainer, 2003; Maag Merki et al., 2010; van Beek, de Jong, Minnaert & Wubbels, 2014). Our results indicate that the implementation of a new teaching perspective is enhanced by the possibility to discuss ideas and topics with teaching colleagues and research partners. The results of the interviews also suggest that this wider communication strengthens the development of a sophisticated concept of self-regulated learning that may encourage teachers to gradually introduce more self-regulated activities in their teaching.

In the training sessions we emphasized teacher initiatives which specifically aim to engage students in self-regulated learning. The teachers implemented these new strategies only partially in the lessons observed and maintained external regulating activities (lecturing, questioning, explaining) as well. This might be down to the fact that the process of learning to regulate requires sharing cognitive experiences by means of metacognitive comments and discussing the processes (Flavell, 1987). This interpretation is supported by the frequent reflection on the problem solving processes in class by the teachers as well as their incisive comments during the interviews with the collaborative group.

Some limitations of the study have to be taken into account: the sample of teachers was quite small. Further, only one observer monitored the classroom interactions so that the reliability of these data cannot be assessed. We consider this study therefore as a pilot study. The results should be thoroughly tested by means of a larger number of teachers and classes. The perspective of the pupils should then be taken into account as well. The collaboration period lasted less than half a school year and was too short to ensure that long-term and stable collaborative practices in the school could be established. This result is in line with the results of Kaenders (2010) who reported much longer periods of collaborative interaction between school teachers and university members.

It is a complex and highly demanding task to teach pupils to become more autonomous and self-regulated in their learning. Our study indicates that when teachers collaborate with each other as well as with university partners, a deeper understanding of these complex processes is gained allowing for the flexible application of new concepts in different teaching situations.

The Yalla Program - Integral Framed Support for Young Leaders from Egypt and Germany

Adrian Wagner[1]

Abstract: The article gives an overview of the Yalla program that has taken place in Egypt and Germany since 2012 and was originally initiated by Katharina Petrisson from the Federal Foreign Ministry of Germany in cooperation with Matthias Ruff and the Humboldt Viadrina School of Governance. After an introduction of underlying causes for the uprising in the Middle East, the preconditions of the program are explained. Furthermore the integrative framework that was used to design such trainings is analyzed. The paper also evaluates the online value development assessments of German and Egyptian participants within the Yalla-2-training. As a framework for the case study An interdisciplinary approach was used including developmental psychology, social and political science as well as system theory and action research.

Keywords: Arab Spring, integral theory, intercultural leadership, large system change, Middle East, online value assessment, political capacity building, spiral dynamics, theory U.

Introduction

Who would have expected the spontaneous protests of 2010 to spread like a wild fire through the Middle East and lead to the so-called Arab Spring? From today's perspective, not only the Middle East, but the whole world seems to have been impacted in a way that left it shaking within political, environmental and other sectors. It seems that crises are becoming the norm in a complex global environment. According to Beck and Cowen (2005), integral (yellow) values compose the first second-tier value meme that consciously deals with those complex, global survival issues. Unpredictable dynamics and fast-changing environments require new forms of leadership and dialogue practices between different cultures and sectors. In this article, a case study of the pilot Yalla program that is taken place in Egypt since 2012 and was originally initiated by Katharina Petrisson from the Federal Foreign Ministry of Germany in cooperation with Matthias Ruff will be presented. The program, based on an integral mindset, seeks to support young leaders and change makers in Germany and Egypt who face complex (social) problems. In order to describe the preconditions of the program first a short overview of some of the underlying reasons and strategies that have strongly influenced the dynamics of the Arab Spring will be given. Secondly, it will be explained how these political developments have led to the emergence of the Yalla program with its different projects Yalla I, Yalla II and Dialog Lab I.

SOME RIGHTS RESERVED

The third chapter outlines the vision, mission and goals of the Yalla program in relation to the different projects. Furthermore, some of the fundamental principals, models, concepts and theories on which the program is built are introduced and explanation will be given on why they were chosen. Several *disciplines like developmental psychology, social and political science as well as system theory and action research are included in the paper.* The fifth chapter gives a short overview of the program's achievements up to today and also introduces some early results of an online value assessment tool.[2] Finally, a preview on further intentions and upcoming projects in the near future of the Yalla program will be provided.

(Very) Brief History of the Arab Spring

First of all, why did some regimes survive the revolutions of the Arab world while others were overthrown? Some explanations see the “variety of social, economic, and political factors, including social media (Howard et al., 2011, p. 1), demographic shifts (the youth bulge[3]) and economic grievances like high unemployment and limited social mobility” (Abadeer & Williamson, 2014, p. 1) as the driving forces behind the revolution. Abadeer and Williamson argue that even while those forces helped to “spur the protest movements”, none of them “satisfactorily explain the variance in outcomes across different countries”. Since the Yalla program takes place in Egypt, the author will focus on the development within Egypt. One important factor for the success of Egypt’s revolution is the absence of a “monarchy and oil-wealthy regime” that could “(...) erect more barriers to prevent protest escalation”. This perspective emphasizes that monarchies and oil-wealthy regimes, locked in strong traditional value systems (purple-red-blue), have more power to resist an uprising. Abadeer and Williamson argue that “a military tied to the regime by familial, tribal, ethnic, or sectarian connections would be more likely to support the regime.” (Abadeer & Williamson, 2014, p. 3). The exploitation of embedded tribal value systems (purple-red) within the army structure can often be seen with authoritarian leaders (red-blue) to fight uprisings.[4] However, the military is a rather powerful and independent player within the Egyptian society (some would even state, one with blue-orange motives)[5] that is not tied to certain tribes or ethnic groups per se. Since the beginning of the protests, the military was reluctant to back Mubarak and at some point chose the side of the protesting people. Another key factor is that the Egyptian government had almost no resources to support its own political power structure. This stands in contrast to other Middle East regimes which, again, are oil-wealthy. In Egypt, a broad scale of the poor was involved in the protest movement and could identify with the overall call for “bread, freedom, and social justice”.[6] This might largely explain why the revolution did overthrow the Mubarak regime.

Nevertheless, those given factors and driving forces do not explain or determine the new strategies of the Arab spring. James Gelvin argues that the common aspects of the strategies are that:

1. They were relatively spontaneous;
2. A single party or leader did not lead them; and
3. They used unifying slogans focusing on political demands.

(Gelvin, 2012, p.1)

However, often unnoticed by the western world, is the fact that the “uneventful protests grew organically into movements of masses of people (…)” and that they “were based on the infrastructure built by earlier protest movements” such as the April 6 movement in Egypt. Even if the protest was partly built on existing structures, this cannot fully explain the rapid growth of the overall movement with countless human rights activists and other social groups led to a kind of leaderless movement that could not be prevented, threatened or bought. In addition, the unification of different groups within Egypt was supported by demands that were large enough to unify a wide array of social groups and classes, like rich, poor, leftist, secular, and Islamist groups (Bayat, 2010, pp. 1-3).

Today, four years later, it seems that this pattern reoccurs in many parts of the world as well, considering the protests in Turkey and Brazil 2013 and Ukraine 2013/14. What all these protests movements have in common is that they do not have a single party or leader that leads them. Scharmer and Kaeufer (2013) describe these recent phenomena as a new dynamic of collective leadership that is build on new approaches of activism by stakeholders from diverse backgrounds. In his view, co-sensing, co-creating, generative dialogue and action have become important guiding principals for those new movements.

But what did these protests mean for the Egyptian people? Generally spoken, “*new dreams were born, new desires were discovered, and a memory of a moment where the “present wavered” was etched in every participant’s psyche.”* (Gordon, 2004, p. 5). This can be seen as a collective and unifying state experience. Since this collective eruption in 2011, the social reality in Egypt has changed dramatically due to the violent removal of the former president Mohammed Morsi and the Muslim Brotherhood organizations through the intervention of the Egyptian military. Despite an overall more stable situation in comparison to one year ago, it seems that “the exploitation of knowledge to serve political ends” has returned – a problem that was already identified by the 2003 Arab Human Development Report as the greatest impediment of “the creation of a well-knit Arab knowledge society.”

For this very reason, in the authors perspective the Yalla program wants to establish a knowledge creation community by building sustainable relationships: between young potential leaders within Egypt and Germany and organizations such as Sekem, Heliopolis University and the Start-Up Hub scene. The next chapter will further outline the background of the Yalla program as perceived by the author.

Project History

In autumn 2012, the Yalla program begun with an encounter of 20 young potential leaders (10 German and 10 Egyptian participants) who were involved in projects of different kind that were aiming to shape their political and civil societies in their own countries – Egypt and Germany. The Yalla I project consisted of two parts and started with a five-day training in October, in cooperation with the former Humboldt Viadrina School of Governance in Berlin. The second 5-day-workshop took place in Cairo in January 2013. Because of its success, the project was repeated in November 2013, however, in a denser version as it consisted only of a 5-day workshop in Cairo. The next project related to the Yalla program was Dialog Lab I, which was developed due to the demand of the youth organization Cadre in order to deepen the understanding of developmental psychology and integral theory. In January 2014, the 5-day learning journey took place at the Egyptian organization Sekem[7] and focused more on an in-depth analysis of existing projects of the participants while using Spiral Dynamics integral and systemic constellation work.

The Yalla Program

Before elaborating on the processes and outcomes of the Yalla projects that have been implemented up to now, the author wants to high lighten the overall intention of the Yalla program.

All projects regard attentive and deliberate communication as a key social technology and include several adult development models such as Spiral Dynamics and Ken Wilber’s 4-Quadrant model. These models and theories are practically applied by participants in their own socio-political fields and projects. The idea of the Yalla program was inspired by the commitment and engagement shown by young adults of the Arab world during the past three years, a commitment often driven by idealism and enthusiasm to change their societies.

However, this young generation is facing new challenges within the fields of political communication and with regard to complex problem solving. In the authors view, the Arab spring is an example of “the various waves of disruptive, revolutionary change that redefine the context” (Scharmer, 2000, p. 3) not only within business, but within societies as a whole. This is also illustrated by a qualitative German study (Leipprand et al., 2012, pp. 4-5) within which several executives and leaders within politics, business, science and civil society have been interviewed. According to the authors, new leadership skills are required on a global level as the main leadership challenges in the beginning of the 21 Century are:

1. Growing complexity:

   Greater transparency is driving up the number of stakeholders and increasing the pressure for decisions to be made quickly. At the same time, projections and forecasts are becoming less reliable. Consequently, executives are losing control.

2. Insufficient Reflection:

   The challenges of day-to-day business leave little room for long-term thinking. Managers allow themselves insufficient scope for regeneration and reflection. The use of values to guide decision-making appears to be gaining momentum.

---

[7] Sekem started as a biodynamic farm and, with its 1700 employees, is one of the biggest sustainable businesses in Egypt. They recently founded the Heliopolis University outside of Cairo.

3. Walls between sectors:

> Structural and cultural barriers prevent the sectors of politics, industry, civil society and academia from working together as they need to. In place of cooperation there is mutual indifference, and, in some cases, even antipathy.

In order to face these challenges, the Yalla program wants to support the development of complex system thinking and problem solving by offering a space for reflection. At the same time, young potential leaders from different sectors meet each other and valuable relationships for the future can be established. Furthermore, the Yalla program strives to approach the concept of leadership with a differentiation on an *individual, organizational and societal* level (Leipprand et al., 2012) which is based on Scharmer and Kaeufer (2013). In their book, the authors address, among other topics, the possible causes of these upcoming leadership challenges within an 'Iceberg Model.' They distinguish several problem areas ('bubbles') that manifest in three major divides within societies (ecological, social and spiritual-cultural divide), as illustrated below:

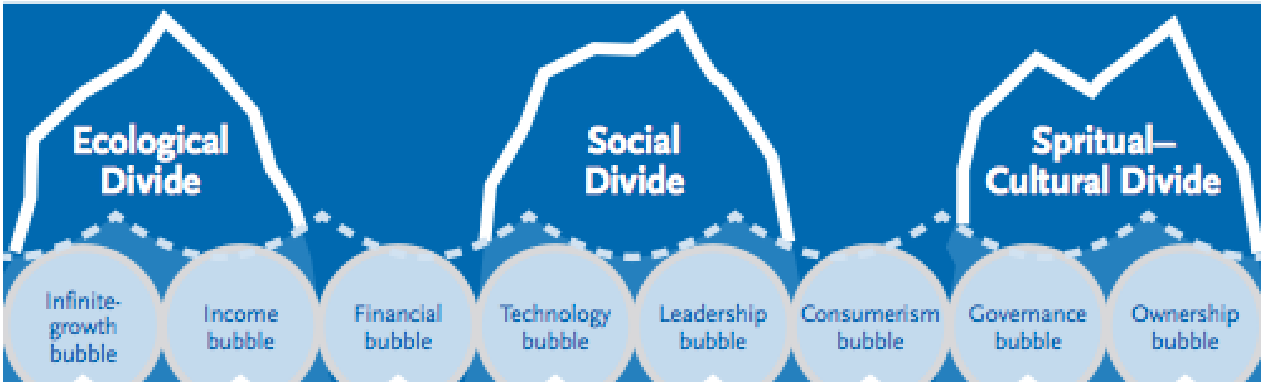

Figure 1: The Three Divides. (Scharmer & Käufer, 2013, p. 14. Used with permission).

The Yalla program makes young leaders aware of all eight potential crises areas with a focus on the leadership and governance bubbles. These insights will immediately be exemplified and experienced while focusing on challenges that the participants are facing in their own political and social projects. The Yalla II as well as the Dialog Lab I project put more emphasis on the understanding of how to let key players from political institutions, non-governmental organizations and businesses collaborate better in order to find holistic solutions.

Principles and Methodology of the Yalla Program

The first Yalla training was designed as a two-week process. In the first week, the trainer Matthias Ruff and Eric Poettschacher focused on theoretical background such as the understanding of Spiral Dynamics and the Four Quadrants as well as an Open Space process. In this process, the proceedings of the second week of the Yalla 1 project was co-created with the participants that wanted to work with organizations in Cairo to test their new tools and knowledge.

Rather then teaching models in a purely intellectual-academic setting, Yalla projects are designed as a container and a space to learn through practicing certain dialogue principals and transformation tools. This includes the concepts and practices of co-creation, presencing and generative dialogue. Furthermore, young leaders are encouraged to explore forms of collective leadership across cultural boundaries. Regarding to integral politics, the Yalla program empowers young leaders to "*embrace any and all interactive process through which the evolving diversity of a community or society engages in consciously co-creating its collective life*" (Atlee, 2010, p. 276. Italics added for emphasis).

Increasingly important within the program gets the task to hold a deep systemic perspective while facilitating the processes similar to the suggestion in Atlee (2010):

> …conversational interactivity is the medium through which different parts of a system can find the coherence—coordination, protocols, and shared understandings, narratives, intentions, etc.—that they need to function efficiently as a whole. From an individual perspective, high quality conversation is a primary alternative to violence as we seek to pursue our self-interest in a world of other self-interested entities with limited perspectives. (p. 279)

Through those high quality conversations, an experience of "flow" states (Csikszentmihalyi, 1990) can be reached to tap into resources of collective intelligence and whole-system engagement. The principle of personal mastery (Senge, 1990), an interior-individual dimension within leadership, is therefore crucial considering the challenges that lay ahead of the presently young generation. From a facilitator's perspective, we are committed to a co-learning process with the participants in the process. This is the reason why we incorporated action research as one model within the Yalla program. According to Gilmore, Krantz & Ramirez (1986) action research in this context

> ...aims to contribute both to the practical concerns of people in an immediate problematic situation and to further the goals of social science simultaneously. Thus, there is a dual commitment in action research to study a system and concurrently to collaborate with members of the system in changing it in what is together regarded as a desirable direction. Accomplishing this twin goal requires the active collaboration of researcher and client, and thus it stresses the importance of co-learning as a primary aspect of the research process. (p. 161)

The Dialog Lab I training was designed as a learning journey[8] with conceptual support by the 'four moods of knowledge creation' by Ikujiro Nonaka.[9] Each day in in itself was designed as a learning spiral. In the mornings, an overview of a particular part of Graves' developmental model[10] was given to the group. Participants would have access to our knowledge and learn about certain aspects of the theory by internalization (explicit knowledge creation). In the next step, they would share their experience, brainstorm about the day's topics in a none-judgmental way and observe their own reactions within role games to illustrate e.g. the previously presented value systems (tacit knowledge creation). Afterwards, the participants and facilitators would design a wall with pictures, statements, anecdotes and analogies on a big sheet of paper where they related to and experienced the particular value system to externalize their knowledge (explicit knowledge creation). The last step was to deepen the knowledge though examples of best practices (combining knowledge).[11] This helped to deepen knowledge in a holistic way and to make it useful for the participants and their work context.

[10] http://www.integralleadership.com/the-graves-values-model.php

In the next part of the article, the author will focus on the outcomes and goals that were achieved with the Yalla program so far.

Case Study: A Prototype of Online Value Assessment

One important tool tentatively used in the Yalla II training was an online value assessment tool developed by Dr. Marc Lucas which is called "Word Pairs".[12] This online test provides some insight into the participants' values and basic convictions that influence their decision-making, thus showing in what respects their conclusions might deviate from those of their potential dialog partners and reference persons. According to Marc Lucas the test is build on „the early and trend-setting insight of Graves (2005) about the necessity of integration and a neurobiological basis of adult development theories within the framework of a bio-psycho-social paradigm was the starting point for the model-theoretical considerations and the research design."[13] Even if Graves work is largely unknown in academic circles due to the early death and little empirical research has been published till date, it has won a lot of interest just lately. For example, Strack (2011, p.22) has published an empirical study in which evidence is found, that Graves' theory and Schwartz's typological theory of the universalistic value circle (Schwartz & Bardi, 2001; Schwartz, 2006) which is dominant in today's value research are based on the same value structure.[14]

Lucas follows the original idea of Graves to „describe a neurobiological correlate of the theory by using a tachistoscope". In graves study he presented specific value terminology „to test persons for a few milliseconds at a time. Terms that corresponded to the dominant effective value system of the test person were recognised more quickly than other terms. The word pair online test from Lucas transferred Graves original idea „into an up to date research design backed by fMRI (...) in his leadership and adult development study developed in partnership with the University of Cologne and the Institute of Neuroscience and Medicine.[15] The word pair test is used within the Yalla program to provide suggestions for improving participants' communication skills and behavioral patterns in key conflict and decision-making situations, as well as generate data on possible intercultural differences between German and Egyptian participants.

[13] http://baojournal.com/BDB%20WEBSITE/archive/BDB%2019.4-F.pdf, p. 84
[14] Ibid.
[15] Ibid.

Within this first testing, six German and six Egyptian participants volunteered by doing the online test. In the word pair test, participants are confronted with word pairs consisting of different values related to seven developmental levels according to Graves' model. Because of the small number of participants, the results at present cannot be seen as a substantial study that provides empirical evidence. Nevertheless, certain outcomes indicate possible trends for further research. The aim of the prototype was not to analyze individuals, but to get an overview of basic values and convictions within the German and the Egyptian group of participants.

Participants did the testing anonymously via an online link that was sent via email to open a personal account for the testing. The test started with a few questions on the participants' age, education and gender. Within the word-pair test, participants were successively presented 400 word-pairs and had to choose within 2.5 seconds which word they preferred over the other. If they required too much time, they repeated the word pair at the end of the test. The results are presented as percentages for each of the seven different value systems, with longer reaction times suggesting that participants have a higher distance to a certain value system, or might not be as familiar with it. The reason for the time limit is to evoke the spontaneous/intuitive response of people rather then having them think about what the appropriate answer could be. Within the graphics below, the average reaction time of German and Egyptian participants and the average preference for certain value systems are shown in percentage.

In the German group, the average reaction to choose purple value memes is 0,4 seconds lower (1.7 seconds to) then the Egyptians average reaction time (2.1 seconds). Interestingly, the value preference for purple within the German group is also 7 % higher than the Egyptian group. Should this trend be validated in the future, several explanations are possible. First of all, the participants are selected through a questionnaire for the trainings, and they usually represent the highly educated and the young leaders from both sides. The lower preference for purple within young, well-educated Egyptians might mirror their social context. Lower preference for purple values and a stronger preference for red might also be an indicator for their experience within the revolutionary struggle for independence and freedom. This result should, of course, by no means be confused with the average Egyptian value meme preference. Elza Maalouf argues in her interview that the value preference of countries within the Middle East is still focusing strongly on red-purple-blue value memes, while individuals within the young Generation Y (particularly women) are trying to shift into more complex value memes.[16] In Germany, a stronger purple orientation towards family/purple values might be the young generation's reaction to a more fragmented, competitive and pluralistic society, as is also indicated as a “Regrounding” in the Sinus youth study 2012.[17] The biggest difference (over 10 %) between Egyptians (40.1%) and Germans (30.3%) is found within the red value meme preference. This might be in alignment with the Elza Maalouf and Dr. Don Beck's above-mentioned findings. From a cultural perspective, I would argue that Germany might be a country were red values are still associated with strong aggression, abuse of power and violence and therefore is less accepted within society. An alternative hypothesis is that certain cultural barriers related to the German history might prevent the development from purple to red within Germany.[18] The overall strong preference for modern/orange values within the German group is an indicator for the scientific-based higher education and the economic well-being within the German society. Additionally, green value memes have been rising in the German context since the seventies, leading to the foundation of a green party and the recent decision to abolish nuclear power plants. A surprising result is presented by the low yellow value preference of the German participants (50.1 %) compared to the relatively high preference by the Egyptians (56.2%). One possible reason rooted within Egyptian culture could be a stronger multi-active social behavior of Egyptians which might be more willing to embrace yellow values while a more linear-active culture[19] is more reluctant to shift into an integral value system. Another reason could be the multi-level challenges young Egyptian leaders are facing on different value levels within Egypt. Those persons might be more aware of the necessity to include/integrate very different values within a society. The societal state of Germany, on the other hand, is quite stable and economically sound. Centered in orange/green values, the need to shift into more yellow/integrative values might not yet be seen or felt by young people due to the overall good performance of the economy. Another possibility is the overall more balanced value preference within the Egyptian group. The lowest value preference in red (40.2 %) differs by only 17% to the highest value preference in green (57.7 %), while within the German group the low red value preference (30,29 %) differs by over 32 % from the orange value preference (62,5 %). It could be argued that this strong variation suggests no need for strong individual assertiveness (something you might well need and learn in a revolution) given the relatively secure and stable German cultural and societal context. Overall, the test will, on a long-term base, provide substantial data for the design of the Yalla program and can be developed into a tool to monitor and support the developmental journey of the participants on a regular basis.

Goals Achieved by the Yalla Program

In this chapter, the author gives an overview what the Yalla program has achieved so far and how it might be developing in the near future. Every single project aims to be a learning lab for all participants, which has as a central point the involvement of the two different cultures of Egypt and Germany.

In the beginning of the Yalla I and II project, a questionnaire was sent to the participants. The key question was how participants can support each other so that their projects can deepen, develop and unfold to have an optimal impact. The questionnaires sent to participants before the project showed that they had three main requests. Those requests led to the following workshop design:

1. There was plenty of time and space during the workshops in Berlin and Cairo to discuss the development of the concrete work the participants were doing.

[18] Rossmann describes this in a blog entry http://integralesleben.org/if-home/il-integrales-leben/anwendungen/gesellschaft/deutsch-sein-ein-neuer-stolz-auf-die-nation-im-einklang-mit-dem-herzen/

[19] http://magnussonllc.files.wordpress.com/2011/01/lewis-model.jpg

2. In addition, there was the possibility to generate new and common ideas. Through the different explanatory models, new perspectives on the different projects were depicted to show and unfold their effectiveness.
3. In the scope of this project, it was very important to the participants that they had the chance to exchange ideas, build relationships and new networks (as intended by the facilitators). While in the Berlin part of the training, models and concepts were explored and discussed, the Cairo Workshop of Yalla I was taking the newly gained knowledge into practice.

Through an Open Space Café at the end of the Berlin Workshop, four fields of interest were identified and small groups of five people came together to find a potential partner organization within a particular field (youth education, minorities, sustainability, integral politics, religion & politics). Egyptian organizations working in corresponding fields were approached by the participants and visited twice during the Cairo workshop. One day provided the groups with the opportunity to analyze and get to know the organization, whereas the second day contributed in a precise way to the organization's work: If the organization agreed, the groups were implementing an intervention based on the methodology of Spiral Dynamics and integral theory. Within the integral politics team, the Egyptian Democratic Organization was supported though a role game on funding possibilities and value creation within the organization. In another group, a youth education organization was coached in respect to how to deal with the fluctuation of volunteers within the organization. Furthermore, according to the participants' personal feedback, several other goals were achieved:

- Participants achieved a deeper understanding of political communication through a systemic perspective.
- Participants of both sides engaged in a still ongoing dialogue concerning the political situation in Germany and in Egypt.
- The workshop contributed to enhance the participants' cultural sensitivity and competence and helped each participant to understand their specific challenges better.
- The Yalla I and II project also supported participants in discovering new ways to discuss actual, relevant situations in their field of expertise and how to find potential solutions for them.

While this was also the case in the Dialog Lab I, a stronger emphasis on knowledge creation, spiral dynamics and the collaboration with Sekem (bridging business, civil society and politics) enabled us to support young leaders and change makers on a personal level and Sekem as an institution on an organizational level. The idea of a social innovation lab within Sekem and the Heliopolis University was formulated; furthermore, the systemic dynamics of the revolution in 2011, the current situation in Egypt (January 2013) and a vision of the future (2030) was visualized by the participants through a facilitated systemic constellation.

What is Next

As a conclusion to this report, the author would like to give an insight into possible future plans within the Yalla program. The next step might consist in the implementation of the Dialog Lab II project that continues the concept of an intercultural exchange between young potential leaders from Egypt and Germany. The participants should have the opportunity to communicate and experiment freely in the safe and beautiful setting of the Sekem community. The Dialog Lab II could then:

- be a learning lab for both cultures involved
- empower participants through sharing of knowledge and ideas
- use creative tension between the German and Egyptian culture (linear and multi-active) as a resource for prototyping solutions
- focus on long-term project of young participants in relation to education and green technology in Egypt
- fostering and including indigenous intelligence.

Through the word-pair test and possible additional tests more research could be conducted in the future. On a personal note one important idea for the author is to move from theory into action and from action into theory in order to ground and development an integral transformation approach. On the long term the Yalla program should also in the view of the author monitor and support the different projects and participants (long-term) to add an interior dimension for the understanding of transformation within a political context (German Foreign Office) which is still mainly focused on outer factors such as economic and legal reforms and is missing on crucial factors such as value assessment, indigenous intelligence and mesh working (Maalouf, 2015).

Transformative Learning for Climate Change Engagement: Regenerating Perspectives, Principles, and Practice[1]

Gary P. Hampson[2] & Matthew Rich-Tolsma[3]

Abstract: In this position paper the worldview from which climate change continues to occur is identified as late modernism. This worldview is critiqued as being unduly economistic, reductive, mechanistic, and fragmented. There is a clear requirement for an inclusive and transcending transformation of this worldview toward one substantively more able to meet the challenges that climate change presents, as well as an understanding of the processes that facilitate such a transformation. This paper foregrounds transformative learning as a generic process that might well be key to this transformation. The paper addresses transformative learning both as an active process and as a feature of a regenerated worldview, identified here with respect to Griffin's reconstructive postmodernism, which goes beyond deconstructive postmodernism in its proto-integral orientation. Transformative learning is exemplified by the seminal approach of Mezirow as well as Scharmer's *Theory U*. The discussion of worldview is vertically differentiated in terms of principles, worldview perspectives, and sectoral practice with reference to the depth ontology of Inayallatulah's *Causal Layered Analysis*. Principles addresses the regeneration of the philosophy of science, and explores the critical contrast between atomism acting as attractor for modernism, and complex integration acting as attractor for reconstructive postmodernism / the ecological worldview; it indicates the fecundity of Bhaskar's critical realism for aptly addressing climate change. Sectoral practice is represented by higher education, specifically addressing andragogy, heutagogy, the transformative learner, and the transformative educator. Climate change is a complex, big-picture issue, one that requires a complex, integrative epistemology and transdisciplinary orientation.

Keywords: Causal layered analysis, climate change, complex integration, ecological worldview, transdisciplinarity, transformative learning, sustainability, worldview.

Introduction

Contemporary climate change[4] is induced by one species, the same species that is now considering its possible, probable, and preferred futures arising from the consequences of its actions. Yet all species are affected, as indeed is the entire biospherical fabric of our shared existence. Contemporary climate change is quintessentially a big-picture issue. Planetary, long-term, complex, deep, multifaceted, and involving all cultures, all memes, and all known life-forms, climate change calls out for approaches of engagement which aptly address and carefully integrate a myriad of fields including those addressing the physical, the ecological, and the psycho-socio-cultural. To understand how we reached this point, sufficient depth of philosophical, historical, and depth-cultural analysis is necessary; to most effectively move toward our best realistic futures, we not only require futures thinking but also suitable processes which enable us to make the necessary transformations of thought, affect, and behaviour authentically and efficiently. We need to regenerate our world into something we want before it degenerates us into something we do not want.

In this article we suggest that transformative learning is a useful signifier to encompass the cluster of various processes – able to be used in a variety of individual and collective contexts – which adequately enable such transformations at both individual and collective levels. We believe that the potential usefulness of transformative education in addressing climate change has not been explored sufficiently and this paper therefore attempts to valorise transformative learning as one appropriate approach to facilitating the worldview shift required to address this wickedly complex challenge. We attempt to unpack transformative learning through the lenses of (philosophical) perspectives, (scientific) principles, and (sectoral) practice. Each of these provide useful – to some degree irreducible – lenses to assist piecing together the numerous angles, which the complexity of climate change demands. This symbolises the understanding that climate change is a complex but singular ontology requiring an aptly analogous complex but incisive epistemological tapestry. Specifically, the lenses used here can be interpreted according to a vertical schema such as Causal Layered Analysis (Inayatullah, 1998).

After situating the current interest within a review of climate change discourse, we address the layers of perspective and principle, respectively. This is followed by a discussion of the social sector of higher education. Finally, a "hermeneutic circle" of learning is also facilitated through the deepening iteration of transformative learning as a topic in the perspectives and practice sections.

The key normative orientation regarding the need for – and direction of – regeneration is given by the critical contrast between the worldview of modernism (with its underlying principle of atomism), deconstructive postmodernism and that of reconstructive postmodernism[5] (with its underlying principle of complex integration). The central idea is that the latter, but not the former, is suitable for an eco-logical future - one in which climate change is most adequately addressed in thought and action. Transformative learning is both an object of inquiry and the process by which many of the insights discussed in the paper have arisen and can continue to arise. It forms the core process within the preferred emerging worldview, and so forms the introduction to that section.

---

[4] For current data concerning climate change, see Brown (2008) and the Earth Policy Institute's website (http://www.earth-policy.org/data_center/). One should also note the various "revealing and concealing" related to each term in the cluster of signifiers that includes *climate change*, *global warming,* and *global heating*.

[5] The term *reconstructive postmodernism* was coined by Griffin (2002). He identifies it as "a diffuse sentiment…that humanity can and must go beyond the modern" (p. vii), where the modern worldview is identified in relation to "Galilean-Cartesian-Baconian-Newtonian science" (p. vii). Griffin differentiates

Reviewing Climate Change Discourse

Climate change discourse can be identified in relation to sustainability discourse and, more generally, to environmental discourse, which itself has begun as a complementary movement to modern times out of the Romantic streams of philosophical thought following the Enlightenment (see Hampson, 2010c, 2013). *Silent Spring*, Rachel Carson's (1962) expose on the harmful effects of industrial pesticides is largely credited with launching the contemporary environmental movement by awakening an awareness of the urgency of the ecological crisis in popular consciousness (Glausiusz, 2007).

Following the 1972 UN Conference on the Human Environment in Stockholm – the same year as the Club of Rome's *Limits to Growth* report (Meadows *et al.*, 1972) – the somewhat contested notions of "sustainability"[6] and "sustainable development" (the latter developing from around 1980[7] at the beginning of the neoliberal era) have gradually systematized environmental discourse in various ways (Kaivo-oja, Luukkanen, & Malaska, 2001). A spectrum involving economistic (neoliberal) imaginaries at one end and deep ecological attractors on the other can be identified. To date, the former appears to be the dominant mainstream interpretation (Howarth & Norgaard, 1992). The geneaology of the economistic interpretation (Lerch & Nutzinger (2002) and Kaivo-ja, Luukkannen, & Malaska (2001)) includes: early neoclassical economic growth theories that incorporate natural resource constraints on the economic doctrine (e.g. Hicks, 1946; Solow, 1974; Page, 1977; and Hartwick, 1977), The Safe Minimum Standards approach (Ciriacy-Wantrup, 1952; and Bishop 1978, 1993), The London School Approach (Pearce et al., 1990; Klaasen & Opschor, 1991; Pearce & Turner, 1990), Daly's Steady-State approach (1990, 1992), The World Bank's neoclassical approach (1992), and The Wuppertal approach (Femia, Hinterberger, & Renn, 1999). Selby & Kagawa (2010) offer a firm critique of this perspective with respect to its uptake in education:

---

between re/constructive and deconstructive (or relativistic) postmodernisms, inferring a complex relationship between them such that they both share the idea that "a massive deconstruction of many received concepts is needed," yet the deconstruction "is not so totalizing as to prevent reconstruction" (p. ix). The vector of this reconstruction is toward "a new unity of scientific, ethical, aesthetic, and religious intuitions" (p. ix) involving "a creative synthesis of modern and premodern truths and values" (p. x).

[6] There is no complete agreement concerning the meaning of sustainability. In an attempt to clarify the multiplicity of opinion, Varey (2003) has collated over 100 separate definitions from a wide diversity of sources.

[7] World Conservation Union's strategy document (IUCN, 1980); elaborated upon at length by the so-called Brundtland commission's report, *Our Common Futures* (WCED, 1987) and the 1992 UN World Conference on Environment and Development, Rio de Janiero (United Nations, 1993).

> Education for sustainable development (ESD) is the latest and thickest manifestation of the 'closing circle' of policy-driven environmental education. Characterised by definitional haziness, a tendency to blur rather than lay bare inconsistencies and incompatibilities, and a cozy but ill-considered association with the globalisation agenda, the field has allowed the neoliberal marketplace worldview into the circle so that mainstream education for sustainable development tacitly embraces economic growth and an instrumentalist and managerial view of nature that goes hand in glove with an emphasis on the technical and the tangible rather than the axiological and intangible. Runaway climate change is imminent but there is widespread climate change denial, including within mainstream ESD. A transformative educational agenda in response to climate change is [called for]. (p. 37)

In response to such critiques – i.e. interpretations at the other end of the spectrum – lie the more complex perspectives of the deep ecological approaches which tend to support the evolutionary emergence of a zero-growth society (Daly, 1992). They variously include Capra's (1982) web of life, Naess's (1989, 2005) *Ecosophy T*, Guattari's (1989) ecosophy, Shiva's (1988, 2007, 2008) Vedic ecofeminism, Berry's (1991) ecotheology, Macy's (1991, 2005) work that reconnects, and Lovelock's (2000) Gaia hypothesis.

Facilitated by popular accounts of the crisis such as Gore's (2006) *An Inconvenient Truth*, the profound effects of climate change have now become part of mainstream discourse. Unfortunately, mainstream media continue to present a decidedly biased account of the science (Readfearn, 2013) such that the American public, for example, think that only approximately half of climate scientists are in agreement regarding the understanding that climate change is human-induced, whereas in reality over 97% of climate scientists have been in consistent agreement for at least twenty years (Cook et al., 2013). It is clear that such data indicates the urgent necessity of advancing the *social (e.g. political) science* of climate change and its importance to mainstream understanding.

Academic discourses on climate change have been primarily oriented by technological innovation (e.g. regarding alternative energy), with additional reference to social innovation and systems transformation perspectives (e.g. Hardin Tibbs, 1993) – or an integration of these (e.g. McDonaugh & Braungart, 2012; James & Lahti, 2004). Despite these burgeoning innovations, however, evidence continues to indicate that the crisis is worsening. Why might this be the case? Unruh (2000) argues that technological industrial complexes emerge through complex adaptive interactions among technologies and institutions. Once lock-in to a particular technological industrial complex occurs (in response to a "strange attractor") it can become extremely difficult to displace, and can serve to lock-out other emergent technologies. The lock-in conditions are often exacerbated by governmental and legal structures. The whole system can then form dynamically stable sociotechnical regimes (Geels & Schot, 2007). This is the case for late modernity's addiction to both carbon technologies and industrial-scale livestock agriculture – both in the face of viable alternatives. The latter, which accounts for approximately 18% of greenhouse gases, is of critical importance, given its relative under-emphasis not only in popular discourse but also in the academic literature.

This highlights the importance of exploring the cultural and relational aspects of sustainability in terms of social and individual transformation. For instance, Bouwen & Tailleau (2004) point to an important dialectical relationship between relational and problem-solving strategies, which may be seen as an integration of interior and exterior perspectives (Wilber 2000). Some attempts have been made to expand beyond traditional definitions of sustainability in light of these limitations; these include work by Brown (2006); Zimmermann (2005); Herrera (2005); Esbjörn-Hargens (2005); Varey (n.d.); Reason, Coleman & Ballard *et al* (n.d.); and Ballard (2005). In addition there is a growing body of work explicitly addressing the psychological aspects of sustainability, including the psychology of sustainable behaviour (Manning, 2009), conservation psychology (Saunders, 2003), and the development of the ecopsychological self (John & McDonald, 2007). Of particular note is the role of worldview (Lynam, 2012; De Witt, 2013).

Whilst transformative learning is identified as being very useful for education regarding ecological sustainability and climate change (Lange, 2004; Wals, 2010), it is considerably under-emphasised. We hope to contribute to rectifying this situation, and in so doing, to help regenerate perspectives from those of late modernism and early postmodernism to those of an ecological or reconstructive post-postmodern worldview.

Regenerating Perspectives

This section addresses the regeneration of worldview. The first part introduces transformative learning as key process through which worldview can be regenerated, whilst the second part addresses the overarching conceptualisation of worldview change. We start with transformative learning – as represented by a focus on the work of Mezirow as well as Scharmer's (2009) *Theory U*.

Transformative Learning

The term *transformative learning* was originally coined by Mezirow (1978a). He first identified transformation as a valuable educational idea while conducting research in the late 1970's with women returning to postsecondary education or the workplace after a protracted absence. He was interested in exploring the factors that impeded or facilitated meaningful and successful re-entry experiences; his discoveries led him to a number of valuable realisations concerning the nature of learning. Notably, he evolved a new definition of transformation as "the process of using a prior interpretation to construe a new or a revised interpretation of the meaning of one's experience to guide future action" and concluded that "transformative learning occurs when there is a transformation in one of our beliefs or attitudes (a meaning scheme), or a transformation of our entire perspective (habit of mind)" (Merriam, Caffarella, & Baumgartner, 2007: 132). Mezirow's original model (1978a, 1978b) is normally understood in terms of ten stages of transformation, namely:

1. A disorienting dilemma;
2. A self-examination with feelings of guilt or shame;
3. A critical assessment of epistemic, sociocultural, or psychic assumptions;
4. Recognition that one's discontent and the process of transformation are shared and that others have negotiated a similar change;
5. Exploration of options for new roles, relationships, and actions;
6. Planning a course of action;
7. Acquisition of knowledge and skills for implementing one's plans;

8. Provisional trying of new roles;
9. Building of competence and self-confidence in new roles and relationships; and
10. A reintegration into one's life on the basis of conditions dictated by one's perspective.

At first blush, one can begin to see a mapping (from individual to collective) onto the issue of climate change. For example:

1. Climate change as a disorienting dilemma, one which humanity has not had to face before;
2. What collective guilt lies lurking beneath our hubris and denial regarding the mass extinction of species that is concurrently occurring?
3. The need to perform a socio-cultural psychoanalysis;
4. Joining forces;
5. Exploring possible and likely future scenarios;
6. Identifying paths toward our *preferred* scenarios (within the bounds of realism) – what complex socio-cultural structures are involved?
7. What competencies and capacities do we need?
8. What prototyping might we conduct?
9. The need for ongoing co-empowerment;
10. Identifying the ideal of the regeneration of our socio-cultural fabric into one that is (at the very least) ecologically sustainable.

Kitchenham (2008) indicates the major influences on Mezirow's early work as being Thomas Kuhn's (1962) notion of paradigm shifts (regarding the structure of scientific revolutions); Paulo Freire's (1997) notion of conscientisation and dialogical action; and – from 1981 – Jürgen Habermas's (1971, 1984) domains of learning, namely, the technical, the practical, and the emancipatory.

Mezirow has continued to refine his theory over the last three and a half decades. Specifically, Mezirow (1985) distinguishes three types of learning – the instrumental, the dialogic, and the self- reflective – each of which comprise three possible learning processes – learning within meaning schemes, learning new meaning schemes, and transforming by learning through meaning schemes. Another significant refinement is Mezirow's (1998) distinction between two types of critical reflection on assumptions: (i) *objective* reframing of narrative and/or action; and (ii) *subjective* reframing of critical self-reflection on assumptions manifesting as narrative, systemic, therapeutic, and epistemic. A third significant contribution to the theory is the addition of four domains of transformation: (i) elaborating upon existing frames of reference,[8] (ii) learning new frames of reference, (iii) transforming points of view, and (iv) transforming habits of mind (Mezirow 2000).

Broadly speaking, transformative learning integrates multiple understandings of the notion of transformation (Dirkx, 1998), including (i) transformation as critical reflection – the category with which Mezirow is most identified, (ii) transformation as consciousness-raising – identified primarily with Freire (1997), (iii) transformation as development – most explicitly identified with

---

[8] Frames of reference, in this sense, may be understood as embodying two components: habits of mind, which are broad-based assumptions that serve to filter our experience of life, and resulting points of view, attitudes, beliefs, and judgments.

Larry Daloz (1986) but also those who understand development as a transformation in consciousness (Merriam, 2004) – such as Sri Aurobindo (1975), Jean Gebser (1956), and Robert Keagan (1994), and (iv) transformation as individuation – primarily associated with Robert Boyd (1991; Boyd & Myers, 1988).

The vectors identified above (from Mezirow's points of departure) constitute a variety of ways in which there can be a transformative regeneration of perspectives. This ecosystem of understanding can be fruitfully complemented by a more recent addition to transformative learning – that of Otto Scharmer's (2009) *Theory U.*

Theory U facilitates an experience of social presence which enables a group to illuminate collective blind spots inherent in social systems with the aim of co-generating and co-leading transformation. The process takes the general shape of a "U":

1. The left hand "downward" movement comprises (from top down) *suspending* patterns of the past through open mind > seeing with fresh eyes > *diving deep* through open heart > sensing from the field > *letting go* through open will;
2. The bottom of the U comprises *presencing* (connecting to Source (Jaworski, 2012));
3. The right hand "upward" movement comprises (from bottom up) "*letting come*" through open will > crystallising vision and intuition > *enacting* through open heart > prototyping (co-creating strategic manoeuvres) > *embodying* through open mind.

It can be noted that the holistic dimensionality of this process resonates with a "head, heart, hands" framing, which has been identified as useful for transformative learning with respect to sustainability (Sipos, et al., 2008).

Scharmer proposes that the process necessitates a deep quality of attention and identifies the U as a progressive movement through four fields or structures of attention: field one involves operating from the old "me-world;" field two comprises moving into the current *it* (exterior) world; field three involves operating from the current "you-world;" whilst field four addresses the highest future possibility that is wanting to emerge. He argues that a movement from the reactive postures of field one to the more integrative and transformative impulses of field three and four are needed in order to create change throughout a complex system. On a micro (individual thinking) level this correlates to moving through four levels of *listening*: (i) downloading habits of thought, (ii) object-focused listening, (iii) empathic listening, and (iv) generative listening. The act of opening and surrender empowers the emergence of novelty by illuminating blind spots that we normally allow to be obscured by assumptions and superfluous thought. The process can be identified as involving five movements:

1. *Co-initiating*: generating collective intent, taking time to listen deeply to others, and tune into where life is leading us;
2. *Co-sensing:* opening ourselves to emergent possibilities and potentials through careful observation;
3. *Presencing:* surrendering our wills and connecting to the deep and still source of inspiration; in the midst of this deep silence an inner sense of embodied knowing is empowered to arise to the surface;

4. *Co-creating*: exploring what prototypes of the new might look like and imagining how they might translate into real world action;
5. *Co-evolving*: holistically embodying and facilitating the ecosystemic emergence of the new.

In relation to climate change, the proposition is that the efficacy of appropriate transformative change would be significantly enhanced through employing Theory U processes.

Transforming Worldview

Theory U employs a vertical schema to facilitate the regeneration of perspectives. As indicated in the introduction, a further vertically oriented model that orients the paper is that of Causal Layered Analysis, and its explicit inclusion of the worldview layer. To recap, Causal Layered Analysis conceives four layers of social reality. From surface to depth, these comprise:

- The litany layer;
- The policy or systemic layer;
- The worldview layer; and
- The layer of myth, metaphor and principles.[9]

News broadcasts and newspapers tend to focus on the litany layer, whilst policy-making operates at the systemic level below. In contrast to these two, the underlying layers of worldview and myth-metaphor tend mostly to operate unconsciously. Therefore, the system by which policy is oriented does not tend to question its basic premises. It tends to rest upon a business-as-usual paradigm as much as possible. The scope of climate change, however, demands a deeper engagement. It demands explicit address of the worldview and its concomitant "essences," metaphors, principles.

The work of Annick Hedlund-de Witt (2013) explicitly addresses worldview in relation to sustainability, entailing implications for climate change. She identifies that the structural (economico-socio-cultural) barriers to changing lifestyles are deeply embedded in worldviews and that research indicates that the dominant worldview is the central barrier for the transition to a more sustainable society. Yet "despite their apparent importance, worldviews tend to be underemphasized in the sustainability field" (p. 12). Moreover, she expresses the idea that a certain form of science can actually hamper efforts to the extent that it falls prey to *scientism* – involving an "excess of objectivity" Sarewitz (2004) – to the detriment of apt inclusion of interior (Wilber, 2000) perspectives (e.g. aesthetic experience, emotional responses, psychological dynamics, religious meaning, ethical issues, and cultural values (Esbjörn-Hargens, 2010a)) as indicated by *worldviews* (De Witt, 2013).

There are various levels of generality one might identify with respect to the concept of worldview. At one end of the spectrum, it could be understood that each person carries a different worldview. Heading toward more clustering of understanding, a wide range of worldviews could be identified regarding the wide range of demographic categorisations such as culture, age, or socio-economic status. At the most general level, however, we might wish to consider broad sweeps of zeitgeists, both dominant and more marginal. At this level, we can identify such worldviews as "traditional," "modern," and "postmodern." Given that undesired climate change is associated with modernism – through such activities as fossil fuel use and industrial husbandry, it would be hard to adequately argue (though many attempt to) that we should somehow pursue a slightly modified business-as-usual approach. No. A more developed reconstructive postmodern worldview is called for. Such worldview comes in a variety of shapes and sizes, and not all might be fitting for the adequate address of climate change. The worldview proposed here is in the general camp of an ecological or reconstructive post-postmodernism [refs], one involving complex-integrative, postformal-integrative or integral thinking [refs]. Such thinking requires not only the address of its own understanding of climate change, but it also needs to be able to adequately understand and communicate with interpretations of climate change stemming from other worldviews.

---

[9] Principles being an extension of the original conception, as explained above.

Regenerating Principles

Underlying the worldview layer could be myths, metaphors, values, patterns, principles, habits, templates, etc. The following addresses one of these, perhaps a key one – the transformation of modern atomism to complex integration or "eco-logics" (Hampson, 2010a, 2010b, 2011).[10] Such a transformation of principles underlying worldview can be understood in relation to Kuhn's (1962) notion of "paradigm shifts" which makes space for the inclusion of sociological, psychological, and historical viewpoints in the development of scientific knowledge.

We first discuss the general context of paradigm change in the philosophy of science. This is followed by a more explicit address of the principles of modern atomism and complex integration.

Philosophy of Science

It can be argued that a hindrance to apt climate change engagement comprises the current ideology or (mythic aspect) of science as distinct from the essence or core of scientific process, one involving appropriate inquiry at all levels. A pertinent context is that natural science to some interpreters often appears to be in inadequate dialogue with its philosophical roots whereby the role of scientist devolves into that of mere technician. The following historical context provides a lens that might be helpful in addressing the contemporary configuration of the philosophy of science.

Although science substantively developed in the classical Islamic civilisation (see Hampson, 2010c), its dominance only took hold in the modern era. Somewhat in response to the abuses of the Christian Church in the Middle Ages, modernism – and thus modern science – increasingly rejected metaphysical perspectives. A consequence of this is that it "flattened" the once-existing vertical ontology into a single strata; moreover, the single strata that it adopted was the lowest stratum, that of "fundamentals" (as represented by physics and chemistry). One might say that molecules were prioritised over meaning. However, whilst address of fundamental layers is important, they are not necessarily the most significant aspects of reality. The short-term (in historical time) success of scientific address of these fundamentals to produce modern technology and its concomitant material comforts consolidated this "lowest common denominator" tendency. But we now find ourselves with a human-induced atmospheric-heating feedback loop, the cause of which we are not only not abating, but actually increasing. The good news is that modern science has adequately delineated the physical condition (i.e. that at the fundamental ontological stratum of atmospheric chemistry). The bad news is that humanity's collective actions to date give the impression that "no one is listening," or, perhaps more accurately, that those that are listening do not appear to have sufficient power in relation to the structures which govern collective human activity, that there are conflicting voices, many of which are fuelled by partisan interests. This understanding can be unpacked yet further, of course. And it needs to be. But this is precisely where social science and the arts and humanities step in with respect to climate change. Yet the most helpful insights that could be found here are thwarted by:

---

[10] The atomistic←→eco-logical dimension is, of course, not the only one that can be used to distinguish the preferred worldview to the present hegemonic one. It is, for example, important to address "principles of affect," so to speak – emotional values which charge the worldviews. This is a complex matter, but certainly a move from *greed* as (mostly) unconscious motivator to *care* as (more) conscious motivator would be in order. To assist in this, the classical question *What is the Good Life?* needs to re-enter the centre of the conversation of culture and politics.

- The lower status (overall) of this aspect of contemporary academia as opposed to natural science and the "pragmatic" subjects of business, accountancy and technology (noting that "pragmatic" is rarely interpreted as "pragmatic for the planet");
- The undue "weight" of natural science paradigms attempted to be applied in the social sciences – notably regarding positivism; and
- The dominance of institutional disciplinarity – a form of modern atomism – such that there is insufficient integration or coherence between insights arising from natural science and those from the arts, humanities and social sciences.

Another is that the entire academic endeavour – regardless of philosophy of science employed – appears to be thwarted by an apparent anti-intellectualism in the political sphere whereby there is insufficient adherence to policy recommendations. Humanity's academic mind is working but the political "body" seems to be governed instead by lower drives – short-termism, greed; a global politics blinkered, obfuscating, partisan. Of course, there are many exceptions. Indeed, there is a groundswell of alternative thinking and action, too. Such transformative approaches have the potential to transform the collective outcomes of human activity – but only if there is a change of societal status of pertinent knowledge in the transition to a more ecologically sustainable world.

In relation to the above, transformative principles would include:

- The regeneration of politics through adhering far more closely to policy recommendations arising from such transdisciplinary climate change research; and
- The prioritisation of pertinence (Morin, 1999) – along with the paradigms that support this – in the arts, humanities and social sciences. Such pertinence is facilitated by apt coherence between "the two cultures" of natural science and the humanities – empowering transdisciplinary understandings, and entailing the reinvigoration of philosophy and meta-theorising suitable for a deep ecological era.

The paradigms, philosophies and meta-theories entail regeneration via the principle of complex integration. It is the contrast between this prospect and the current default of the principle of modern atomism to which we now turn.

Beyond Modern Atomism

As indicated above, climate change is a quintessentially complex, big-picture issue. So, it would be hard to argue that apt engagement with it does not therefore require a like-minded epistemological orientation. The current default way of engaging does not adequately meet this requirement. Rather, it falls prey to modernism's – often hidden – tendency to be oriented by atomism or fragmentation. Where integration *is* attempted through modernism, the default is toward a reductionism or over-simplification (e.g. a "theory of *everything*" – in physics discourse – as constituted merely by *fundamental* particles rather than recognising more complex ontological levels include realities irreducible to fundamentals). Modern atomism shows itself in myriad ways throughout the institutionalisations of this kind of thinking in society. In academia, an instance where it shows itself in an undue reliance on disciplinary structures to the detriment of transdisciplinary orientations (Nicolescu, 2008).

Modern atomism is a remnant of the import of classical physics' conception of atoms as billiard balls. It underlies much technological and bureaucratic thinking. Its imaginery comprises units of similar character with non-complex identities; it focuses on these units to the detriment of both the relations between them and the identity of the whole system within which the atomistic identities are situated. Consequently, the pertinence of contexts, diversity, interactivity, and complex causal patterns is underplayed (Hampson, 2010b, 2011).

The principle of atomism that forms part of the layer beneath the modern worldview needs to be regenerated into a more complex and integrative one, one more resonant with the ecosystemic complex that is humanity-within-biosphere. Ecologies of the life-world require the development of ecologies of mind (Hampson, 2012). These ecologies of mind, or eco-logics, could manifest in a variety of ways. But a sense of the whole and a sense of the various dimensions of complexity need to form part of the mind-set. Oriented by this regenerated principle – that of complex integration – the approaches of critical realism, ecosophy, and postformal integral theorising variously represent facilitations toward an eco-logical future.

With respect to the explicit conceptual location of philosophy of science, critical realism counters both fundamentalised positivism and fundamentalised constructivism or relativism through adopting a more realistically complex picture of the whole, including the normative. In this way, critical realism comprises a philosophy of science adequate to meet the challenges and complexity of climate change (Hedlund-de Witt, 2013) (with its ecosystem of current and potential normativities), particularly with regard to the different understandings required to confluently address the physical world, biospherical ecosystems, and the psycho-socio-cultural sphere.

The following section exemplifies this panoramic sense of the critical and the real by focusing on the regeneration of the sector of higher education, a social location key to fostering a transformative worldview.

Regenerating Practice

The regeneration of principles and worldview perspectives has implications for practice. Education is potentially able to be efficient in facilitating the profound changes necessary, and, indeed, is potentially the dominant locus of transformative learning. In this article we have chosen to address higher education as indicative.

Higher education in late modernity is multifaceted. One could say it is both part of the problem (through its reinforcement of climate-change-inducing ways of thinking as per atomism) and part of the solution (such as through its constructive analyses of the problem). Higher education is also undergoing significant changes. Some are facilitative of new, apt ways of learning and being, whilst others reinforce late modernism's grip – the demise of the arts and humanities in favour of business-related courses, for example. We argue that such so-called economism is actually a form of sectarian, ego-driven, short-term interest; what is *pragmatic for the planet* is ignored. If a long-term systems perspective is considered then the arts and humanities become highly pragmatic given the desirability of global reflexive consciousness. Moreover, the strong institutional inclination toward disciplinary structures – in contrast to transdisciplinary frames – thwarts integrated attempts to address climate change as a quintessentially big-picture and multifaceted issue. What is needed is the new norm of a financially empowered, rigorous (but not rigid) transdisciplinary orientation toward climate change. This includes transformative engagements with the pertinent contexts of climate change (past, present and possible futures for humanity and other life forms), exploration of the various paradigms of consciousness and a focus on rational inquiry beyond the limitations set by conventional thinking.

In short, apt address of climate change requires transdisciplinary frames in order to prioritise and coordinate the various types of understandings arising from the natural and social sciences, the arts and humanities.

For further discussion of transdisciplinarity as a suitable complex integrative form of *curriculum* to facilitate futures adequately addressing climate change, please see Hampson (2012); and for further discussion with respect to complex integrative approaches in general regarding higher education, please see Hampson (2011) and Hampson & Rich-Tolsma (forthcoming). The discussion below focuses instead on transformative learning *processes*, and concomitant character of learner, teacher and occasion.

Andragogy and Heutagogy

As learners develop cognitively they become increasingly rationally emancipated, mature, and functionally autonomous (Mezirow, 1997). This development takes place in inverse proportion to their need for scaffolding, instructional support, and cultural mediation (Canning & Callan, 2010; Kenyon & Hase, 2010). Blaschke (2012) therefore proposes that there is a natural developmental progression from the concept of pedagogy (*leading the child*) built upon teacher-lead student engagement, to andragogy (*leading the person*) oriented by the student-centred notion of learning cultivation, to heutagogy (*leading the self*) resonant with the notion of self-realisation (Canning, 2010).

Transformative higher education addresses the last two. Whilst andragogy can be identified as self-*directed* learning (Knowles, 1975; Merriam, 2001), heutagogy may be understood as self-*determined* learning involving the development of competencies and capacities (Hase & Kenyon, 2000; 2007). Here, the learner becomes “the major agent in their own learning, which occurs as a result of personal experiences” (Hase & Kenyon, 2007: 112). One of the key characteristics of a heutagogical approach is double-loop learning and self-reflection (Argyris & Schön, 1996). As learners take ownership for the determination of their own learning and transformation they begin to interrogate deeply held beliefs and assumptions underpinning their actions (Eberle & Childress, 2005; Hase, 2009) thus initiating “virtuous cycles” of learning. Mezirow indicates that this process involves a critical reflectivity comprising four types of subjective reframing:

- *Narrative* – the application of narrative critical reflection of assumptions to oneself;
- *Systemic* – critical inquiry into inter-objective factors and influences (e.g. the organizational, political, social, and ethical);
- *Therapeutic* – a careful phenomenological appraisal of our feelings and reactive thought patterns in order to apprehend the foreseeable effect they may have on our actions; and
- *Epistemic* – the interrogation of the causes, nature, and consequences of our very frame of reference.

Such transformative learning processes can occur in both individual learning and collective learning (Kilgore, 1999) contexts. Regarding the address of climate change, empowerment of the latter would be particularly appropriate given the global nature of the crisis.

We end with indications regarding the changing roles of learner, teacher and learning occasion. The following account regarding transformative human identity (Hampson, 2005) presents an amalgam understanding oriented by approaches such as those of Mezirow (1981; 1991; 1997), Baumgartner (2001), Daloz (1986; 1999), Dirkx (1997), Taylor (1998), Morin (1999), Kincheloe (2005), and Montessori (1988) in addition to drawing upon the experience of the current authors.

The Transformative Learner

The student encountering transformative learning is no longer a mere educational consumer, but rather a transdisciplinary scientist-scholar-practitioner deeply engaged in self-determination and the apt transformation of their world. This requires that learners have sufficient developmental maturity to explore the perspectives of others and cope with their own shifts in paradigm; that they are ready and open for change; that they are willing to make self-reflection an integral part of their lives in multiple contexts; and that they strive for pertinent knowledge, courageously engaging the complex multiplicity of perspectives. Their journey forms part of a (perhaps non-linear but progressive) emancipation enabling them to name their own world (Freire 1997, p.89) , rather than merely regurgitating social realities defined by cultural institutions. It might also be seen that learners with diverse (positive and negative) life experience have an increased likelihood of cultivating transformation.

The Transformative Teacher

Analogously, transformative educators are no longer a mere technician charged with administering an educational commodity, nor are they a guide through the predictable terrain of a curriculum. Instead, they serve the roles of mediator and companion; they become the enabler of the students' self-determination and social emancipation: teacher as catalyst for transformation. This includes facilitating emotional intelligence,[11] and critical awareness (critical thinking and critical theory).[12]

The Transformative Occasion

The learning occasion as a whole thus becomes transformed into one in which the planetary, the complex, and the holistic are welcomed, encompassing multiple perspectives and states of awareness. Understanding is embedded within deep purpose and individual biography. Transformative processes such as Theory U are employed in order to access apt ways forward. These may also entail processes from the arts and the physical, as well as entailing a sense of exploration between different perspectives, toward the engendering of respect, empathy, deep dialogue and collegiality,. Additionally, outer architecture is consciously designed as a reflection of the "inner architecture" of transformative curriculum. Overall, there is a sense of global citizenship deeply rooted in a worldview striving towards ethics for the human species and other sentient beings, a worldview that facilitates appropriate address of climate change through the many dimensions of transformative learning.

Ends-in-View

Apt engagement with climate change involves the transformation of the dominant worldview of humanity. Whilst it has achieved much, modernism has been insufficiently ecological; it has been overly simplistic, and inadequately attentive to the full range of human potential and social well-being. The new worldview needs to be deeply ecological, complexly integrative, and transformative. Transformative learning – both individual and collective – is a key process in helping regenerate our worldview in such a way. It also derives from the new worldview, one that pays apt homage to non-Western understandings, to the pre-modern West, and to alternative (e.g. Romantic) streams of human consciousness. The new worldview entails a major shift of principles, requiring the reinvigoration of epistemology and a highly developed review of the philosophy of science. Careful discernment should be applied to both science and economics to separate out their core good from ideological distortions, including collusion with partisan interests. The latter should be deconstructed; the former should form the core of a new appropriate principle of science and economics. The practice of transformative learning should be understood as an open system, one occurring in many contexts, both formal and informal.

---

[11] *Facilitating emotional intelligence*. *Interpersonally*, this includes facilitating and modeling sensitive relationships towards and among students, for instance by transcending (or at least acknowledging and suspending) one's own prejudices and striving for a fuller understanding and empathy towards others. *Intrapersonally*, this includes mentoring students in the habit of reflexive self-criticality, especially through constant humility and self-reflection (including blind spots).

[12] *Facilitating critical awareness*. Facilitating critical thinking involves the explicit qualities of open-mindedness and deep inquiry. This often leads to facilitating insights arising from a critical theory orientation. These could involve the planet as a whole, and the economico-socio-cultural context. They might also involve the more specific context of education – the different purposes that different educational institutions have pursued, any hidden curriculum, the influence of power relations, and the context of knowledge production, particularly with respect to alertness to reductionism.

The depth of the climate change issue indicates the appropriateness of employing processes of engagement with it that have analogous levels of depth. Transformative learning is a signifier that coheres various processes that have such a depth – the depth, one might say, at which diamonds are made. This paper has indicated that such learning occasions enable the regeneration of deep layers of our individual and collective being – the regeneration of perspectives and principles which have the ability to most effectively engage with the uniquely challenging predicament which is now presenting itself to humanity. The particular depth regarding perspectives that we have addressed can be identified as – at least – worldview. Worldview is often unconscious and yet guides many of our activities. Even further: beneath worldview can be identified deep imaginal patterns and habits, archetypes, myths, metaphors, paradigms and principles – also mostly unconscious. These underpin, give life to, and maintain their respective worldview(s). In addition to addressing the layers of worldview perspectives and metaphors/principles in general, the paper has also focused on higher education as social sector to explore these deeper layers in particular contexts with regard to the challenge of climate change.

It is hoped that the advocacy of transformative learning as presented here inspires such depth-processes to be creatively employed in the myriad contexts of climate change engagement. Maythe movement outward and onward be accompanied by a development inward and upward . It should become natural to love the Earth.

Welcome to this issue of *Integral Review (IR)*! We are pleased to welcome readers to a new regular issue that brings together a number of articles, essays and reviews.

We are also glad to finally launch our new website! This is the culmination of significant investments in thinking about how we can better serve our readers and make the most of the wealth of content that has been generated here over the years. We also have been thinking about how to make it easier for an even broader audience to become acquainted with this body of work. Towards this goal, we are hoping that being able to better utilize social networks (easy links to share through various social media) and updated functionality (the new site works on smartphones and tablets as well as having a search function) will encourage growth in the community of readers making use of IR.

We also hope these upgrades will stimulate more submissions coming from both familiar and new sources. As we settle into our new home online, we will look to undertake new initiatives to enable a broader footprint for the quality of thought IR fosters. Look for updates on this on our home page and through our newsletter.

This issue has three peer reviewed articles, two essays, a poem and three extended book reviews and a response. The peer reviewed articles include reporting on qualitative research using Sara Ross' *The Integral Process for Working on Complex Issues,* action research using Wilber's AQAL model in the field of diversity in higher education and a theoretical inquiry into Kegan and Lahey's Immunity to Change process.

The two essays include a look at archetypes in relation interpreting research in leadership studies and stories of encounters with an extraordinary person. These are followed by a poem and three reviews. One review examines two books related to new forms of economy, another about integral development and the third about leadership. This issue closes with a response to the final book review. We are pleased to provide readers with this range of quality research, reflections and reviews.

Pia Andersson brings us *The Dynamics of Hope and Motivations in Groups Working on Complex Societal Issues* to open this issue. She has been doing extensive research on how using The Integral Process for Working on Complex Issues (TIP) affected participants' sense of personal hope and motivation. Andersson goes into depth unpacking the nuances and contexts for how hope arises and affects motivation. As well, she goes into the relationship between participants' experiences of hope about smaller specific aspects of issues compared to the feelings arising from seeing more of the complexity of issues.

Cheryl Whitelaw has been working in the field of intercultural education as well as linking this to her work as an integral coach. Her weaving of these fields with her her role at a community college and a research project has led to her contribution to this issue of IR; *Developing an Inclusive Perspective for a Diverse College: Inclusion = Diversity + Engagement*. Whitelaw reports on applied research addressing an issue that is relevant for many

SOME RIGHTS RESERVED

colleges and universities; how to improve intercultural communication skills among student service staff to better serve the growing diversity of student populations. The developmental approach and model arising from this work will be of use to many.

For the past four years I have been reflecting on links between what I perceived as relevant insights from different theoretical perspectives on Kegan and Lahey's Immunity to Change process. These reflections finally took the form of a serious inquiry, leading to the article *Immunity to Change Revisited: Theoretical Foundations for Awareness Based Practices for Leadership Development*. Using qualitative research software to support an analysis of textual extracts from three sources, I discuss implications for ITC as an exemplar of awareness based practices for leadership development. This focuses around the notion of the virtuality of self and how awareness is the embodied realization of this.

Opening our editorially reviewed section, Nathan Harter brings us his inquiry *On the Archetypes Hermes & Hestia: Notes toward a Hermeneutics of Leadership Studies*. This essay explores first the nature of these archetypes, and then their relevance for leadership studies. The use of our imagination in interpreting not only acts of perceived leadership, but also the texts about those acts, becomes essential as we search for deeper layers of meaning in leadership.

We continue with a lovely set of stories by Al Erdynast, providing a window of insight into the world of Stella Adler. His essay *Stella Adler: You Have NO Expertise on Costume*, shows us facets of the human experience of someone with an exceptional degree of expertise and competency in the world. Erdynast describes the impact his experiences with Adler as transformative and his telling of them makes for engaging reading.

Kristian Stålne brings us a poetic interlude with his *Subject Object Poem*. Beyond its deceptively simple title, this poem invites us into a world of reflection and consideration of notions of self and identity.

Book reviews in IR have a long tradition of going well beyond short critiques and summaries of a work. The three reviews in this issue continue that tradition by engaging a variety of lenses and reflective stances in providing readers insights into the works being reviewed.

Kristian Stålne continues this issue with his integrated reviews of Said Dawlabani as well as Otto Scharmer and Katrin Kaufer's works in the field of economics in *Orange Capitalism – and then what? A review of two books on the future of economy and society*. The financial crisis of 2008 brought about, among many things, an accelerated interest in mapping out the future path of economic activity in order to find our way into a new world that somehow can transcend the ills of this current one. Stålne goes into depth comparing and contrasting the two developmental frameworks presented by these authors and reflects on the implications of a developmental approach to studying economics.

Wendelin Küpers continues with his review of Alexander Schieffer and Ronnie Lessem's work in *Review of Integral Development*. He views this book as a culmination of what the authors have done in numerous prior works and finds it to be an aspirational, programmatic and practical agenda outlining what needs to be done to better conceptualize and enact more integral forms of development.

My own review of Anderson and Adam's book *Mastering Leadership: An Integrated Framework for Breakthrough Performance and Extraordinary Business Results* examines how this book aims to bring an integrative approach, including adult development theory, to a mainstream business audience. The core message presented is clear; higher performance in terms of business results is correlated with inner work, or gains in terms of stages of consciousness. My review provides some context for the book, an overview and remarks related to my assessment of the successes and limitations of the endeavor.

We close with a response from Bob Anderson and Bill Adams to my review of *Mastering Leadership*. In their response, Anderson and Adams address some of the critiques presented in my review, presenting a helpful and detailed background on the use of stage development research in the model used in the book.

We hope this issue of *Integral Review* provides you with a useful diversity of perspectives on a variety of topics to inform and enrich your repertoire of knowledge and pique your curiosity for ongoing inquiry. We also hope that you enjoy our new website and take advantage of the possibilities it brings.

The Dynamics of Hope and Motivations in Groups Working on Complex Societal Issues

Pia Andersson[1]

Abstract: This paper reports results from a study of how participants' sense of personal hope and motivation was affected by a facilitated process in which four groups of people worked on different complex social issues. The group interventions were designed to scaffold increased understanding of the complexity of the chosen issue. A method called The Integral Process for Working on Complex Issues was used in all of the groups. Issues addressed in the four groups were: neighborhood deterioration, lack of community engagement, the need for better strategies for communication between rescue service actors in critical life-and-death situations, and transition to a more environmentally sustainable city. The study investigated the participants' self-reported changes in their levels of hope regarding the possibility of achieving positive results on the selected issue, and changes in their motivation to engage in work to that end. The data were gathered through interviews with individual group participants before and after the group process. The sessions supported group members to develop more awareness of the complexity of the issues, and to develop strategies for action.

The study indicates that the discovery of new potential pathways to manage an issue, through a more comprehensive understanding of the complexity involved, was a key factor influencing levels of hope and motivation. Reports from participants showed that when the participants formulated concrete actions that made sense to them, then "particularized hope" emerged, as well as motivation to continue to engage. Thus, increased levels of hope about a delimited part of the issue were reported, while in some cases, participants reported having less hope about the issue complex as a whole.

Keywords: Collective efficacy, engagement, hope, motivation, pathway perception, scaffolding, task complexity awareness.

Introduction

The roles that hope and motivation play when groups gather to work on issues of considerable complexity—especially those with a history of disappointments and failures—can be assumed to be significant, and may be affected by changes in awareness of the task complexity involved (Jordan, 2014). Examples of such complex issues are ethnic segregation in suburbs, city pollution and littering, land use conflicts, and violence against officials on duty.

---

[1] **Pia Andersson** is a PhD student at the Department of Sociology and Work Science, Gothenburg University. Her academic training has a base in theories and practices of conflict resolution, and adult development theories. She has a long practical experience in facilitating various types of group processes. Over the last nine years, her research interests have primarily been focused on methods for working with complex issues, especially for facilitating participatory processes, both in public dialogue and organisational development.

SOME RIGHTS RESERVED

The purpose of this study was to elucidate the relationship between hope, motivation, and awareness of complexity, when groups worked on complex societal issues using a structured discourse for issue analysis and discussion. Factors that influence levels of hope, and the motivation to engage, need to be understood better, as do the interrelationships and dynamics between these dimensions. How the interaction of emotion and cognition influence deliberative processes is not wholly understood (Delli Carpini, Cook, & Jacobs, 2004), and research on the interrelationship between hope and motivation when groups spend time to analyze complex issues of public concern has to my knowledge not been carried out.

Four groups of concerned stakeholders participated in the study, based in Sweden, and the changes in their self-reported sense of hope and motivation before and after participation were analyzed. Each group was offered a facilitated, structured group process as support.

The study is based on a dialectical constructivist perspective.[2] Empirical data were collected to reveal the patterns of how participants constructed meaning about issues of concern to them, as well as how they felt about the possibility to achieve favored outcomes. The main objective of the study was the inquiry into how these patterns changed through a group process, and what consequences this could have for the participants' experience of hope, motivation and for their concrete actions.

The Issue of Defining Hope

The topic of hope spans several research fields, from philosophy and psychology to social and medical science. In the literature, hope has been characterized in a variety of ways, such as an attitude, a disposition, a social habit, a psychic force, a psychological asset, or in terms of process, activity or inquiry (Allec, 2004; Brackney & Westman, 1992; Cooke, 2005; McGeer, 2004; Nalkur, 2009). Hope has often been portrayed through dichotomies, (Jacoby, 2003; O´Hara, 2011) as either goal-oriented or existential; with an emphasis on cognitive elements and agency, or focused on affective features of hope. In a large literature review, Bright (2011) found that definitions of hope could be placed on a continuum, where existential definitions on hope was at one end, and goal-oriented definitions on the other end (Bright, 20011; Jacoby & Goldzweig, 2014).

A dynamic that add intricacy to the understanding of hope, is that what is hoped for can be more or less realistic or dreamlike. This is connected to hope´s close relationship to uncertainty, such as limited possibilities to predict future outcomes, and limited knowledge about which factors may change positively or prove possible to influence through individual or collective actions. Several factors spelt uncertainty adding up to the ever present unknown of the hoped for future (Wolsgård-Krøjer, 2014).

---

[2] Although not so well integrated in my understanding in the beginning, my point of departure was that hope and motivation consist of both cognitive and emotional dimensions. Therefore, to understand the interplay, or – the dialectics – between these dimensions was an important consideration. This point of departure yields a dialectical constructivist perspective, which also got strenghtened as a result of conducting the study. (For a fuller view on the dialectical constructivist perspective, see Basseches & Mascolo, 2010).

While the concept of hope is complex, multifaceted and consequently described in a variety of ways, there seems to be general agreements that hope concerns human engagement with “the issue of possibility” (O´Hara & Ortiz, 2014, p.viii).

The experience of hope is subjective, which makes it difficult to define clearly or to measure, and suggests why the concept of hope has multiple definitions and measurements; some even in stark contrast (Jacoby, 2003; Jacoby & Goldzweig, 2014; O´Hara & Ortiz, 2014; O´Hara, 2011). The functions and effects of hope consequently relate to how the concept is used in the first place. In this study, the relationship between hope for desired change, and the individuals’ motivation to participate in bringing their own capacities to bear on the issue, is in focus. This focus calls for a contextualization of the concept of hope in its relationship to motivation, which will be undertaken in the first part of the literature review. It is also important to define how the concept of hope is used in the study, which I will do in this section.

When attempting to define hope, one stands a risk of reducing the concept to the dichotomies and linear approaches associated with hope studies (O´Hara & Ortiz, 2014; Jacoby & Goldzweig, 2014). The point of departure here is that hope is a complex dynamic with both cognitive and affective elements, and manifest both as a quality of being and as an agentic force. Jacoby (2003) coined the expression “work of hope”, referring to the variability as well as to the developing nature of the experiences people have when speaking about hope. This entails looking at hope from a process point of view, with its inherent dynamics of change. Both hope and motivation involve the dynamic interplay of elements, as “behavioral intentions involve insights into new perspectives (cognition), motivation to act (conation), as well as a new sense of empowerment (affect, or emotion)” (Ross, 2006, p. 149). The research question that this study addresses is how participants’ levels of hope for positive change, and motivation to engage in action towards it, were influenced by the increased awareness of complexity they derived from participating in a facilitated group process. In resonance with this aim, hope and motivation is considered from a process perspective, and as a transitional phenomenon (Jacoby, 2003), which may be influenced by a number of factors over time.

Motivation and Social Context of the Study

Issues are complex when they involve a multitude of different types of conditions and causal relations, when many types of stakeholders with diverging interests are involved, and when stakeholders have dissimilar perspectives on the issues (Jordan, Andersson, & Ringnér, 2013; Rouwette, 2003). If the challenges are perceived as too great, the propensity to make efforts to resolve them is likely to be affected, resulting in pessimism, feelings of powerlessness, blame, or general frustration (Ross, 2006a). A mismatch between the capacity needed to deal with complex issues (DeLauer, 2009; Kegan, 1994; Rosenberg, 2002) and the frustration caused by the difficulty of addressing them gives rise to another set of challenges: how to find motivation to engage when frustration is high and the hope for a solution is low (Inglis, 2010; Ross, 2007, 2009). As passivity, hopelessness, and complacency pose huge threats to the growing need for sustainable management strategies (Ross, 2009), studies that contribute to a deeper understanding of these dynamics could add value to the development of methods for scaffolding the cognitive complexity that appears necessary to address the issues’ complexity. Naturally, if hope and motivation are not sustained when grappling with understanding the complexity of the issue, this will in turn affect the propensity for fruitful deliberations.

Challenges and Support: Scaffolding Complex Issue Analysis

The ability to both notice and handle various dimensions of a complex issue can be referred to as task complexity awareness (Jordan, 2011, 2014), a concept involving the awareness of "the possibility that there might be significant circumstances, causal relationships, potential consequences, and systemic characteristics that might explain occurrences and that might be useful to consider when deciding on a course of action" (Jordan, 2011, p. 60).

When using a structured group process on a complex issue, an important objective is to scaffold task complexity awareness of the issue of concern (Andersson, 2015; Jordan, 2014). An understanding of underlying principles of task complexity (Commons, Trudeau, Stein, Richards, & Krause, 1998) is therefore considered central when designing processes and providing appropriate facilitation for groups working on issues of societal complexity.

On a general level, the concept of *scaffolding* can be explained as a cognitive support structure that enables individuals of all ages to raise their ability and make it possible to complete tasks that otherwise may be too difficult to grasp (Commons & Goodheart, 2008). The term was first used in the cognitive domain as a metaphor for interactional support of children's learning processes (Wood, Bruner & Ross, 1976), but is now widespread in contexts of learning and skill development. In this paper, the concept of scaffolding is focused on the temporary, external support provided by methods and by facilitation strategies.

An adjacent and central role in a facilitated group process is to scaffold increased awareness of how the different stakeholders may reason about the same set of issues, thus increasing the potential for improved communication and understanding (Jordan, 2014; Ross, 2006b). Using a facilitated, structured process for group interaction that scaffolds the exploration of alternative perspectives can bring transformative insights, enabling multiple perspectives on the same issue of concern, resulting in the emergence of new thinking and decision-making (Inglis, 2009; Ross, 2009, 2011).

The Integral Process for Complex Issues (abbreviated TIP)

The cognitive scaffolding that was used to facilitate the group processes is called "The Integral Process for Working on Complex Issues" (Ross, 2006a). It was designed for group processes and was based on analyses of complex issues and theories of adult development. TIP is one of several related methods that aim at dealing with complex issues. Other methods are so-called "problem structuring methods," such as Soft Systems Methodology and the Strategic Choice Approach (Checkland & Poulter, 2006; Friend & Hickling, 2004; Rosenhead & Mingers, 2001).

TIP supports the development of task complexity awareness, as shown in a study using TIP, which hypothesized that participants' level of complexity used to reason about complex issues would increase; binomial test and related measures results were $p < .01$ with large effect size

(Ross, 2007). TIP was chosen for this study for three main reasons: (a) its fit with the research interest as a means to scaffold increased understanding in task complexity awareness, (b) the researcher's own knowledge about how to use this specific process, and (c) the function of TIP as a deliberative process for decision-making.[3]

TIP is a modular, step-by-step approach, in which each step goes deeper into the complex issue that has been selected.[4] This enables an understanding of symptoms of deeper systemic problems and the possibility to identify causal connections. The modular approach of TIP can be visually compared with structural scaffolding, which too is modular in design, so that one can use parts of the construction to complete specific tasks.

The content-free nature of a method makes it replicable, as indicated by a wide variety of uses of, for example, the commonly used SWOT (strengths, weakness, opportunities, threats) analysis. As scaffolding, TIP can be used in a variety of contexts, and regardless of users' diverse issue concerns, to create more capacity for understanding the complexity of a selected issue.

In the next part of the study I survey relevant previous research on hope and motivation. Although there is ample literature about hope as well as motivation, little research has been done that directly relates to group processes, deliberative decision making, and issue complexity. There is extensive research on motivation as a construct, but in this review, the purpose was to focus on motivation in its relationship to personal and public engagement in issues of social concern, and to elucidate the interrelatedness between motivation and hope. While hope and motivation cannot be seen as entirely separate from each other, the differentiation of their relationships is an important part of this study.

After reviewing earlier research, I present the methodology of this study, followed by the results of the data analysis. Finally, there are some concluding comments on the interrelations of hope, motivation, and awareness of complexity, and indications of how these may be important factors to consider for group facilitation when working on complex societal issues. Some recommendations for further research are included at the end.

Previous Research on Hope and Motivation

Some frameworks that serve to unpack relationships between hope and motivation – including differentiations between individual and collective hope – will be discussed in this section. This serves as a background for the study, and is of deep relevance for understanding influences on hope and motivation when scaffolding task complexity awareness in a group process. Because the concepts of hope and motivation are broad, complex, and interconnected, an attempt to outline some of these relationships supports considerations about how a cognitive scaffolding process might affect hope and motivation.

---

[3] Even though TIP was selected as the method used in this study specifically because it was designed to scaffold increased awareness of the issue's complexity among the participants, the purpose of the study was not to evaluate the effectiveness of TIP. TIP was simply an appropriate means for scaffolding awareness of complexity, thereby creating favorable conditions for studying how hope and motivation to engage were influenced by increasing awareness of complexity.

[4] See Appendix 1 for an overview of each step in TIP, or Ross, 2006a, for a full description of the method.

Of particular interest is how other research describes relationships between hope, motivation and issue understanding. This topic concurs with how other researchers have related to, or tried to distinguish, between realistic and dreamlike hope, and expectation, as well as developed explanations for how hope can enhance motivation or lead to passivity.

Research that was found to be of particular interest to the aim of this study will be accounted for at the end of the literature review.

Unpacking the Intricacies of “Hope” and its Relationship to Motivation

While it may be evident that motivation is needed for starting to engage and act—especially when there are barriers to overcome in making substantial changes in issues of concern (Klandermans & Oegema, 1987), hope is often referred to as a prerequisite for motivation, even as a “psychic commitment to life” (Schneider, 1980, as cited in Hinds, 1984, p. 359). From this perspective, hope is viewed as a significant element that affects the motivation to engage in social action, by helping to transform worry into action and to motivate action in the face of uncertainty (Braithwaite, 2004; McGeer 2004; Ojala, 2011; Snyder & Feldman, 2000).

A psychological hope theory developed by Snyder (2000) consists of three cognitive components: goals, agency, and pathways (Snyder, 2000; Green, Oades, & Grant, 2006). The motivational component—agency—is seen “to propel people along the imagined route to the goal” (Snyder, 2000, p. 10). Snyder’s hope theory is based on the assumption that human actions are goal directed and that hope is active when an individual is able to perceive pathways to achieve goals as well as to conceive of the possibility—agency—to act on them.

But the notion of hope as a positive force for agency and action is – as indicated earlier– not agreed on, and a more elaborate understanding is called for. In the literature, contrasting perspectives of hope and its relation to engagement and action appear, indicating polarization or stark contrasts; at some times pointing toward the constructiveness of a hopeful approach, and at other times the opposite (O´Hara, 2011). As it pertains to motivating individual or collective action, a common question in science civic sectors[5] is, how is hope truly conducive to action, and what kind of hope may dampen activity, perhaps resulting in pure passivity (Bovens, 1999; Harwood, 2005; McGeer, 2004; Miceli & Castelfranchi, 2010). While some studies indicate that hope can motivate engaged action, what explanations or definitions might unpack why hope at other times induces passivity?

Miceli and Castelfranchi relate the drive to hope beyond the limits of agency, where “hope implies the mobilization of our energy toward the future because it promotes both our patience to wait for any favouring condition and our readiness to take advantage of such opportunities” (2010, p. 267). From this view, hope can induce an individual to *stay open* to possibilities, even when the odds are low; expectation and hope can diverge, yet favor the tendency to act, “thus orienting one to act in view of the desired event despite the negative forecast” (Miceli & Castelfranchi, 2010, p. 268). This approach recognizes the inherent tensions with hope and uncertainty, and how humans may handle such tensions.

---

[5] See, for example, George Monbiot’s article in the Guardian, http://www.monbiot.com/2012/06/18/the-mendacity-of-hope/ and Derrick Jensen’s article in Orion Magazine, http://www.orionmagazine.org/index.php/articles/article/170/f both retrieved 3 July 2012.

The idea of foolish hope dates back to Plato, who called hope “a foolish counsellor” (O´Hara, 2011, p. 324). Theologian and existentialist philosopher Paul Tillich (1965) distinguishes the quality of foolish hope from genuine hope. Foolish hope is to wait passively for change, whereas genuine hope is to start taking even small steps possible toward living what one hopes for. Here, the focus is on the individual’s ability to take steps to realize valued goals. Choosing a stance of passive hope is sometimes explained as having overly positive expectations of other actors to solve issues of concern to realize one’s hopes (McGeer, 2004). McGeer calls this “wishful hope” and suggests the need for taking more responsibility for agency.

The founder of the Harwood Institute, Richard Harwood (2005), suggests that there is a clear divide between authentic hope and false hope and that there are different *processes* that foster the two. False hope is part of everyday life, for example, automatically trusting expressions by politicians, news media, and civic leaders. Even public opinion tools can foster false hope, by leading people into the false assumption that they have been heard. Well-intentioned community consultation may backfire, failing to create the community engagement it was intended to do, and instead leaving a community with decreased social capital (Hartz-Karp, 2007). By contrast then, authentic hope is ignited in people when they sense that something is true and meaningful, such as when seeing signs of small, but significant steps forward, or when engaging in collective conversations, focusing on real concerns and working together on common challenges (Harwood, 2005). Taking this perspective, a move away from unrealistic, “false” hope, may be a result of a deeper understanding about causal relationships of an issue of concern, and an opening for new, more realistically oriented hopes.

The ability to stay focused on present possibilities, while hoping for future outcomes, is an ability that sets hope apart from positive expectations, according to Miceli and Castelfranchi’s (2010) notion of hope. From this view, hope differs from belief, optimism, trust, and faith, and overcomes the problem of naïve or false hope. The minimal cognitive ingredient is wish and recognition of uncertainty and possibility.

But while uncertainty is intrinsic to hope and may spur action even when the access to knowledge or information appears limited, research shows that when there is uncertainty, or when knowledge is incomplete, the tendency for inaction is higher, as people are less prone to act on uncertain options (Sundblad, 2008). Part of the remedy—to gain understanding—is not sufficient to activate hope and motivated participation; people need to perceive pathways for taking actions that effectively address the issue (Amnå, 2008, 2010; Snyder, 2000; Sundblad, 2008). According to Snyder (2000), gaining access to multiple routes to approaching a goal will positively affect the sense of hopefulness. But the motivation to stay open to new information is needed to seek out new options, which may be difficult when faced with countless obstacles. Hence, when the hoper cannot conceive of possibilities to take action toward that which is hoped for, passive waiting may be the favored approach. However, when there is motivation, the likelihood increases that people will invest more effort in processing a message, which in turn affects the learning process and the ability to recall information (Petty & Wegener, 1998; Sundblad, 2008). Having access to information, as well as being motivated to process it, in turns shapes performance and the quality of decision-making (Druckman, 2004; Kuklinski, James, Quirk, Jerit, & Rich, 2001). Previous research with secondary school students (Persson, Lundegård, & Wickman, 2011) showed how the students were able to transform worry about the environmental issues into action competence[6] and hope. The authors suggest that the combination of listening to the students' ways of formulating their environmental concerns and adapting education to their questions was critical for this result.

The ability to perceive alternative pathways to reach goals and reclaim agency is a central variable for "higher hope people" and "lower hope people" in Snyder's hope theory (Snyder, 2000). Therefore, a significant strategy is to expand and strengthen understandings of pathways by breaking down strategies into clear and relevant steps, finding several alternative and plausible routes to get to the goals, and formulating sub-goals (Lopez, Floyd, Ulven, & Snyder, 2000). This is also an important function of successful scaffolding of task complexity awareness, which can furthermore result in the formulation of new objectives and purposes (Andersson, 2015; Jordan, 2014).

The element of uncertainty of outcome coupled with the perception that things can change for the better (Snyder, 2000; Ojala, 2007), make it hard to predict to what extent hope will complement motivation as a source for engagement. Still, even passive hope may serve as an internal help for an individual to endure a crisis that would at other times be psychologically overwhelming. Snyder and Feldman argue: "Whereas it is true that hope can be pacifying for a period of time, the very same hopeful thinking processes can turn revolutionary when a large number of people feel blocked in their pursuit of valued goals" (Snyder & Feldman, 2000, p. 4009).

As the foregoing discussion suggests, there is a complex connection between hope and understanding, such that assumptions, knowledge, and new information may give rise to fluctuations in the levels of perceived hope. Those fluctuations may affect the propensity to actively engage in realizing hopes.

Individual or Collective Hope and the Impact on (Shared) Motivation

The challenges of collective hope involve sharing visions and managing conflicting goals that may arise when facing issues of societal complexity. According to McGeer (2004), the ability to use one's own powers of agency in pursuing and communicating goals needs to be coupled with a solid understanding of how others may act to either enhance or inhibit their pursuits, depending on the quality of their interactions. Culture and context are also significant factors to consider, even for the role of agency (Nalkur, 2009). Nalkur argues that the self might not always be considered as the agent of hope; instead, supportive relationships and resources can be "more effective agents for hope than the self" (Nalkur, 2009, p. 687). Amnå speaks about "having confidence in one's own ability to work in collaboration" (Amnå, 2010, p. 197) as a measure of collective efficacy and a motive for engagement. Results from previous studies, when using facilitated group processes on community issues, have indicated that stakeholders' confidence in the ability to work together can emerge from developing novel insights together (Ross, 2007; Rouwette, Bleijenbergh & Vennix, 2014).

---

[6] The concept "action competence," as described by Breitung and Mogensen (1999), includes the co-variants knowledge of action possibilities, confidence in one's own influence, and a wish to act. To effectively develop action competence for understanding of environmental issues, approaches that reflect on communal issues and conflicts at several levels, that is, individual, social, and structural, need to be used.

Ojala (2011) refers to trust in other actors as a constructive source of hope and as a necessary condition for collective action. "This source of hope also seems to work as a motivational force, and, thus does not imply that one places all the responsibility for solving the problem on other actors" (Ojala, 2010, p. 12).

A Multidimensional Model of Hope

A framework called *The Multidimensional Model of Hope (*Dufault & Martocchio, 1985) incorporates two spheres of hope: particularized and generalized hope (Allec, 2004; Dufault & Martocchio, 1985; O´Hara, 2014). The framework indicates that there are multiple *processes* of hope that can be active in the same person simultaneously, regarding different objects and events, and through different ways of hoping. Particularised hope emphasises a cognitive component of hope (O´Hara, 2014) as it entails the identification of goals and assessment of task complexity as well as the capacities at hand for achieving specific goals. Generalized hope expresses as a broader scope of future possibilities, without focus on specific results, and can be viewed as a state of mind or life-orientation. This model explains how that the same person can feel very hopeful about certain parts of an issue, while having less hope about other aspects of the very same issue. Further, Dufault and Martocchio apply six dimensions to hope, including affective, cognitive, affiliative, behavioral, contextual, and temporal, which together form the "gestalt of hope" (Allec, 2004, p. 9). O´Hara (2014) proposes a development of this multi-dimensional model, by introducing *transformative hope*. This sphere signifies a way of hoping that may emerge in times of crisis, and lead to new ways of understanding human existence. Transformative hope touches human capacities to move beyond linear thinking, engage paradox and contradictions; enabling a non-discursive awareness (O´Hara, 2014) and the possibility of finding contentment regardless of outcomes. This framework proposes several important distinctions and contributes to the understanding of changes in levels of hope and motivation.

Previous Research of Particular Relevance

Although there are several studies that address different aspects of hope for positive change in societal issues of concern or motivation for personal engagement in issues of social concern (Amnå, 2008, 2010; Axelrod & Lehman, 1993; Inglis, 2011; Klandermans & Oegema, 1987; Ojala, 2007, 2011; Persson, et al, 2011; Ross, 2006b, 2007; Sundblad, 2008), the more specific aim of this study has not been researched in any depth. The aim was to investigate the effects that a more complex understanding may have on individuals' sense of hope for possible change, and their own motivation to address social issues of societal concern. I have found only one study that analyses the effects on hope and motivation of a structured discourse designed to increase complex attention to issues of concern.

In her doctoral dissertation, Ross (2006b, 2007) investigated the effects of using TIP from the beginning step through to deliberation—a total of six modules—in which eight participants from the general public partook. As a result of this finding, a portion of the post-interview was used for rating changes in the participants' hope and motivation about the issue they worked with during their meetings. Results showed notable positive increases in participants' hope and motivation. The most dominant reason given for increased hope and motivation was the "discovery of [a] new system or method to address issues" (Ross, 2007, p. 129); additional reasons included the positive qualities of the people in the group and working together to address the issue. All of the participants reported that the process had provided them with new insights, and half the group reported that they had embarked on new kinds of actions due to new ways of seeing the whole issue (Ross, 2006).

In a case study, Inglis used the deliberative part of TIP during one meeting of nine community members, to investigate the motivation "to engage in public discourse at a level complex enough to make real contributions to the solution for public problems" (Inglis, 2011, p. 13). With support for reflection on the issues of concern, the participants increased the capacity for listening to one another and generating new ideas collectively. Participants reported that the scaffolding that allowed them to consider multiple perspectives acted as a motivator to use an integral process, such as TIP, for future decision-making.

These two studies are the only instances found where researchers have empirically studied how participation in a structured problem analysis process has affected participants' sense of hope and motivation. There is obviously a need for more comprehensive research, involving more cases under different conditions, as well as more participants.

Research on individual motivation within the context of civic engagement and different forms of political participations (Amnå, 2008), showed results that are of particular relevance for this study. Through focus groups with representatives from political parties and citizens that seemed to be politically passive and unengaged, as well as interviews with individuals from non-governmental organizations and activists, Amnå (2008, 2010) found six dynamic and co-existent motives that contribute to some form of engagement, each one increasing the level of motivation to actively engage. These were

1. a sense of obligation,
2. a strong sense of issue-importance or even urgency,
3. a personal sense of ability (including the ability to work collectively with others),
4. having the experience of being needed—"in demand,"
5. being able to perceive pathways for action that addresses the problem, and
6. experiencing meaningfulness (from connecting with other people and developing new social contacts).

Amnå found that people who were more passive or uninvolved did not see the forms of action they could take as having any significant effect. An important emphasis in Amnå´s research is the concept of the standby-citizen, indicating a nuanced view on citizens' potential engagement, and the need for taking a variety of factors into account in order to understand the dynamics that are involved in creating conditions for engagement. The findings conclude that there are several reasons for citizens to engage more actively or remain passive, and that no factor alone can explain everything.

The literature review focused on studies that investigated the role of hope and motivation in individual, social, and civic engagement. The interplay of hope and motivation was shown, concluding that the role of hope may lead to motivation for individual or collective action, as well as inhibit action and results in more passive approaches. Hope and motivation do not necessarily follow a parallel path, and may have different functions and consequences in relation to people's propensity to engage in action. The motivation to engage can be high, even if hope for significant results is limited, and people may have a high level of hope that a problem can be solved, even when they are not motivated to personally engage in working on the issue. Changes in hope and motivation occur dynamically—as a result of several co-concurring processes—and there are multiple reasons for choosing engagement and for experiencing hope.

Methodology

The mixed method study investigated any effects of small group work on concerned people's sense of hope and motivation (willingness to act) after participating in some parts of a structured scaffolding process for working on issues of concern. The focus of the study, then, was not on the groups' issue-related activities during the sessions, but on the individual participants' pre- and post-interviews, in which they used Likert scale ratings and free-form explanations to self-report each individual´s level of hope that the issue of concern with could change in a favorable way, and motivation to actively engage in actions relating to the issue their respective groups worked on.

Participants

Four groups participated in the study, which was conducted in Sweden. For each group, I contacted a key person, who in turn recruited the group participants. The aim was to work with voluntary groups formed by concerned citizens who wanted to address specific issues that were important to them, within non-governmental organizations or self-organized groups. Later, a group from the public sector was added, which contributed to test the scaffolding method in three different kinds of organizational structures and group formats .[7]

There were a total of 27 participants. Each group self-selected a beginning topic of concern, which then became the starting point for the group´s issue exploration, in which TIP was offered as scaffolding. An overview of the groups' contexts, general issues of concern, and participant demographics are presented in Table 1.

---

[7] In Jordan et al, (2013) elaborations on working with different kinds of groups are made, but in this study, the focus is not comparing different outcomes at group-level.

Table 1. Study Groups and Participant Demographics

Group ID #	Context of group	General concern	No. of partici-pants	Age range	Gender	
					Female	Male
1	Public services	Communication between actors in critical life-death situations	7	35–46	3	4
2	Transition Sweden start-up group	Implementing an alternative currency	9	25–78	3	6
3	Swedish Union of Tenants	Community deterioration	6	38–66	4	2
4	Swedish Union of Tenants	Neighborhood activities	5	28–34	5	1

A Brief Description of the Issues that Engaged the Different Groups Public Services

This group's membership consisted of personnel from the ambulance service, SOS Alarm[8], and the police. The participants joined the group voluntarily, although it took place during their working hours.[9] The objective was to find sustainable action strategies to handle the critical and complex issue of incidents where an assembly point[10] is deemed necessary to reduce risks of violence for ambulance staff, while still needing to rapidly attend to citizens who are unwell.

Transition Sweden group: This group of people formed out of their common interest in investigating the idea of implementing a small-scale alternative currency in central Gothenburg and was motivated by a perceived need to gradually transition from the current economical system. Once the participants started engaging in the group process, topics on access to locally produced food and car free zones in the city took precedence, and the group reoriented its purpose.

Tenant groups 3 & 4: The two groups consisted of engaged tenants who were associated with the Swedish Union of Tenants and who voluntarily gathered to arrange activities in the neighborhood. A central issue for both these groups was the exodus of families that had lived in the areas for a long time, along with an ever-growing rate of first-generation immigrants moving in, creating instability and unwanted change. One of the groups was primarily concerned with creating more engagement in the local community, in particular regarding children´s activities and activities for elderly people. The history of negative interaction with local landlords and the Swedish Union of Tenants was also considered a major concern.

---

[8] SOS Alarm is the name for the Swedish emergency service centres.

[9] The participants volunteered to participate, but acted as representatives of their respective organizations.

[10] An "assembly point" is a temporary stopping point set up for the ambulance, if there is a scene that poses a risk for the staff's safety. They wait at this point until the police have secured the scene.

The other group wanted to work with decreasing littering and general deterioration in the area, in order to maintain an attractive community.

Procedures

Data Collection

The data were gathered through mixed-method interviews conducted with the individual group participants before and after their respective group's intervention period. The intervention period was comprised of five (but for one group, six) meetings that involved groups' participation in selected modules of TIP. Thus, pre- and post-interviews were, on average, separated by 6–12 weeks, depending on the group. The groups carried on with activities after the last interview (see Appendix, steps 8 and 9), but these are not included in the data for this study.

Data collection from these four groups, with a total of 27 participants, resulted in 54 total pre- and post-interviews, which were audio-recorded. Informed consent procedures were used according to Swedish standards for all interviews, as well as audio recordings during the group process.

Likert Scale Ratings and Interviews

The data collection involved 5 questions: a Likert style rating system (1) on motivation and (2) on hope. After asking the participants to rate their hope and motivation, respectively, I asked the follow-up question (3), *why do you rate it that way*, to elicit their free-form explanations of their motivation and hope rankings. Additionally, (4) they were asked why they participated, and (5) what they had got from participation. The scale was defined as follows:

1 = not hopeful/motivated at all
2 = between not and slightly hopeful/motivated
3 = slightly hopeful/motivated
4 = between slightly and moderately hopeful/motivated
5 = moderately hopeful/motivated
6 = between moderately and very hopeful/motivated
7 = very hopeful/motivated

Lastly, in the post-interviews, participants were asked to speak about what they had initially wished to get from participating and then asked to speak about what they actually got out of participating. Thus, the interviews generated both quantitative ratings and qualitative explanations.

Data Analysis Procedures

The data from the transcripts of the pre- and post-interviews were coded iteratively, in a qualitative coding manner (Huberman & Miles, 1994). In this way, the different types of factors mentioned by the participants as relevant for explaining their hope and motivation, as well as for explaining any changes after the group processes, were assigned to categories. Multiple iterations of this step-by-step clustering process were executed, which resulted in a final set of categories for analysis. The choice of an inductive approach was made in order to elicit the significant factors that the participants themselves gave as explanations for their sense of hope and personal motivation, rather than measuring a set of proposed categories.

In analyzing the interview data, I was specifically looking for shifts in hope and motivation, and for reasons the participants gave for being hopeful and motivated, as well as reasons they gave for not feeling so hopeful and motivated. Additionally, I looked for pointers indicating whether the sense of hope and motivation was oriented toward specific parts of the issue complex they had analyzed over the sessions.

The pre/post rating scale was used as a concrete measure of changes – increases and decreases—in hope and motivation before and after participation. The Likert-scale is ordered into the total group-level, as seen in figure 2.

Results

This section presents the empirical results of the study. First, the categories found through the content analysis of explanations for levels of hope and motivation mentioned in the interviews are presented and explained. Second, the quantitative data on levels and changes in hope and motivation are shown and salient patterns pointed out. And last, these two phases are integrated and expanded upon in the data analysis.

Explanatory Categories

The analysis of the interviews before starting and after completing the entire group process yielded several different types of reasons for levels and changes in hope and motivation. Some factors acted mainly as sources of hope and motivation, respectively, while others *also* acted as barriers. The following categories were identified in the interview data:

- *Issue importance*—the issue itself was considered important or urgent; thus, it needed to be addressed.
- *Pathway perception*—the respondent perceived meaningful ways to address the issue and take action and felt hopeful because of this, and/or felt motivated to use perceived pathways to work on the issue.
- *Personal resources*—respondents referred to an innate sense of optimism, confidence, strong willpower, talent, time to get involved, keen interest, or valuable knowledge.
- *Collective efficacy*—respondents sensed the possibility of working together toward a shared goal.

- *Other stakeholders*—participants expressed a sense of the engagement or support from actors outside the group, including those with perceived mandates connected with the issue.
- *Process approach*—participants felt motivated by the approach to working on the issue.
- *Goals/future*—participants shared their belief that their vision of the future after changes had occurred was a *source* of motivation.

Two additional categories emerged as perceived barriers to hope and motivation:

- *Structures/systems*—respondents talked about inherent limits in significant organizations or societal structures that would make the issue difficult to solve.
- *Issue complexity*—participants gained the insight that a resolution of the issue might involve more resources than first anticipated.

The categories found in the content analysis of the interviews were compared with categories mentioned in earlier research. Four of the six categories found in this study correlate loosely to Amnå's (2008, 2010) motives; with the exception of "sense of obligation" and "experience of being needed", which were not reasons found for hope and motivation in the data. The naming of three of the categories, namely pathway perception, issue importance, and collective efficacy, were directly inspired by earlier studies (Snyder, 2000; Amnå, 2008, 2010). As seen in earlier research, working collectively on an issue of common concern proved to be a source of both hope and motivation, and perceived support from other stakeholders appeared as both a motivator and a source of hope. The categories process approach, goals/future, structure/systems, and issue complexity did not correlate with earlier research, but emerged from the data.

Levels and Changes of Different Categories of Explanations

Table 2 shows frequencies and before/after changes of participants' uses of the different explanatory categories.[11] These are divided into reasons for hope and motivation, and barriers to hope and motivation.

Table 2. Summary of categories that explained participants' hope and motivation

Categories	**Reasons for hope**				**Reasons for motivation**			
	Before	After	Change		Before	After	Change	
			Qty	%			Qty	%
Issue importance	3	4	1	33%	15	8	-7	-47%
Pathway perception	10	17	7	70%	7	11	4	57%
Personal resources	7	0	-7	-100%	9	6	-3	-33%
Collective efficacy	12	11	-1	-8%	3	10	7	233%
Other stakeholders	6	13	7	117%	2	3	1	50%
Process approach	0	1	1	100%	2	5	3	150%
Goals/future	-	-	-	-	3	4	1	33%
Total reasons cited and net change	**38**	**46**	**8**	**-21%**	**41**	**47**	**6**	**15%**

---

[11] The numbers shown under before/after refer to how many participants mentioned each category during each of their interview. If the same participant (in the same interview) mentioned the same category more than once it is not accounted for in the result.

Barriers due to presence or lack of	**Barriers to hope**				**Barriers to motivation**			
	Before	After	Change		Before	After	Change	
			Qty	%			Qty	%
Pathway perception	10	0	-10	-100%	3	2	-1	-33%

Other stakeholders	10	12	2	20%	6	5	-1	-17%
Structures/systems	4	1	-3	-75%	-	-	-	-
Issue complexity	0	7	7	100%	2	3	1	50%
Issue importance	-	-	-	-	0	3	3	100%
Total barriers cited and net change	**28**	**20**	**-8**	**-29%**	**15**	**19**	**4**	**27%**

Prominent Patterns in Explanatory Categories

The patterns reported in Table 2 indicate that pathway perception was the category most *frequently* given by participants, and the one that was the most prominent explanation for hope as well as motivation *after* participation. The same category was also given as a significant explanation for barriers to hope and motivation before, and had the largest decrease after, participation. Thus, the importance of pathway perception turns up in the data in two ways. First, pathway perception is the most frequently mentioned reason for feeling hope and for being motivated. Second, lack of pathway perception is a frequently mentioned barrier to hope in the pre-interviews, while it is completely absent in comments on barriers to hope in the post-interviews.

Issue importance was the single most frequently given explanation for motivation before participation, while slightly less frequently mentioned after.

Collective efficacy was an important factor for hope before and after participation, and it considerably increased as an explanation for motivation after participation. Before participation, personal resources, such as willpower, interest, or time to get involved, was frequently mentioned as a source of hope, whereas after participation this category was not used to explain levels of hope.

Perceiving support from other stakeholders increased as a reason for hope significantly, and slightly also for motivation after participation. When unpacking the issues' complexity, participants also became increasingly aware that a solution would involve many resources and take time. This was also perceived as barrier to stakeholder involvement: *"I think it* [the complexity] *may discourage some actors*" (post-interview, participant in group 3).

Perceiving a lack of stakeholder support was explained as a barrier both to hope and to motivation and this category increased marginally as a barrier for hope, while decreasing somewhat as reason for motivation, after participation.

Finally, the awareness of issue complexity was mentioned as a barrier to hope after participation, but issue complexity was not mentioned as affecting motivation as strongly.

Participants' Ratings Before and After Participation

Figures 2 and 3 show the changes in individuals' ratings of hope and motivation, averaged by their respective groups, before and after completing their series of meetings. The total ratings for all groups combined show a small, overall increase in both hope and motivation after participation. As indicated earlier, the rating scale ranged from 1 for "not at all" to 7 for "very."

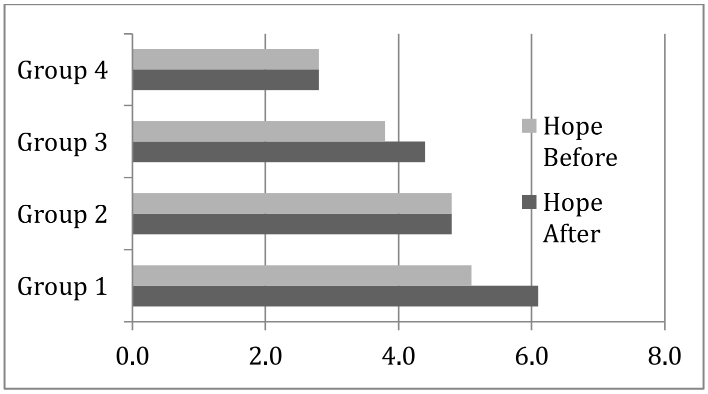

Figure 2. Changes in hope.

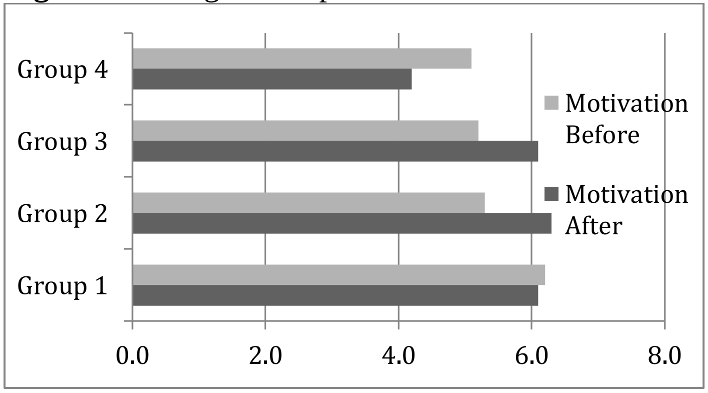

Figure 3. Changes in motivation.

The rates for hope and motivation were altogether higher in groups 1 and 2 than in the tenants' groups 3 and 4. On average, the measures of both hope and motivation were present at the start; only two participants rated "not hopeful" prior to commencing the sessions. The sense of hope that it would be possible to change the issue of concern varied after participation, but only three participants rated it as low as 2 (vaguely hopeful) or 1 (not hopeful). In all groups the rates for motivation were somewhat higher than the rates for hope, both prior to and after the sessions.

For group 1 (public service), there was a significant increase in hope after participation. Group members reported feeling certain that changes would happen, and spoke about pathways for action that they had previously not conceived of, including the implementation of new systems. For example, the group created an action plan for tackling different aspects of the same issue, by creating a guideline that consisted of a step-by-step routine for identifying, evaluating and handling threats. The motivation, which was strong from the outset, remained the same or increased marginally for five out of the seven participants. The group total motivation rate decreased slightly, however, due to two participants' decrease in motivation—one for reasons to do with lack of personal resources, and the other due to experiencing less issue importance.

For group 2 (Transition Sweden start-up group), levels of hope remained the same before and after participation, while motivation increased for the group total rate. A variety of explanations were given for the increase; most prominent were the sense of collective efficacy, pathway perception, and process approach.

In group 3 (tenants), both hope and motivation increased after participation. This group managed to communicate their list of potential actions to change the issue with other stakeholders in subsequent joint meetings; hence, this was the most frequently given explanation for hope after participation. The participants explained that they saw concrete pathways and sensed they could work together to reach common, important goals.

In group 4 (tenants), the rate of hope remained the same after participation, while motivation decreased. Significant for this group was that the experience of lack of support from other important stakeholders that could affect the issues of concern was a strong barrier for both hope and motivation. The group as a whole did not sense that they could affect the overarching concerns for their neighborhood, and their personal resources were waning. For two of the group members in this small group, this also meant that over time they were less concerned about the issue, and instead, redirected their motivations to leaving the area and going to live elsewhere.

Analysis

How Task Complexity Awareness affected Hope and Motivation

An important aim of the group processes was to scaffold increased task complexity awareness. The developing understanding of causation relating to the issues of concern resulted in several types of changes in hope as well as motivation. The participants' changes in understanding of the issues are therefore central when gauging concurrent changes in hope and motivation. There were instances in the data of a reduction of "false hope" (Harwood, 2005), which must be taken into account when interpreting the overall changes in levels of hope and motivation. A reduction in hope is not necessarily a negative result in terms of public engagement, if it means that hope becomes more realistic. This was expressed in a post-interview by a participant in group 2: *"In some ways I have become less hopeful, even if I am still somewhat naïve, perhaps. I think I have gotten less naïve. . . . So I think it will take a longer time and demand more, somehow. It will not resolve itself, like."* In this example, understanding the complexities of the issue leads to a reduction in hope. This was not coupled with lesser motivation, but rather a reorientation of goals, and the focusing of present possibilities.

The complex interrelationship between hope, shifts in cognitive construction of the issue, and motivation is illustrated in the following example, where a participant in group 1 reported an increase in hope, but a decrease in his own motivation to work on solving the issue: *"I am somewhat less motivated now, because I experience that the problem is not as big as some people claimed initially, and in many situations things actually sort themselves out. The mapping of this issue has somehow shown this."*

The group sessions involved analyzing the larger complex of issues in relationship to sub-issues. This resulted in direction for the groups as well as individual participants for strategically working on one or several sub-issues. The development of sub-goals was expressed as an important motivator and as a source of hope. *"I am hopeful about treading the path, but the issue is immense. It will take time"* (post-interview, participant in group 2). In group 1, participants developed communication strategies in the public sector and a whole action system was launched, yet issues of systemic character became apparent during the group process, which were expressed as barriers to hopefulness for successfully working on the whole action system. *"I do not think we will solve the whole issue, but this part of the problem I think we will solve/improve on. I am hopeful about a part, but not the entirety"* (post-interview, participant in group 1). In the tenant group 4, participants reported a sense of lack in support and engagement from other stakeholders, but in one particular issue that had arisen they perceived pathways of action, which involved asking for support from key actors. Three out of five participants reported this as a source of hope for parts of the issue complex, while all of these participants reported less hope for the overall issue concern. These examples show how hope is expressed in the particularized sphere (Dufault & Martocchio, 1985; O´Hara, 2014), as it focuses on specific goals and involves the assessment of task complexity.

The study indicates that the scaffolding approach, which served to increase the awareness of task complexity, may have the effect of reducing hope and motivation, which can be explained by initial unrealistic hope. It may also lead to discovery of new pathways, which increases hope and motivation. The analysis of the data, supported by the study by Ross (2006) and Inglis (2011), indicate an indirect process of scaffolding hope and motivation, where the group sessions helped group members to navigate within the complexity of the issue, and to find some central strategies, rather than becoming overwhelmed by the immensity of the task. Reports from participants showed that when the participants formulated concrete actions that made sense to them, then "particularized hope" emerged, as well as continued engagement. Thus, it was possible to increase levels of hope about a delimited part of the issue complex, even while in some cases having less hope about the issue complex as a whole.

Three Categories that Explained Engagement

Levels of hope and motivation were explained by three categories related to *engagement*; ones' own capacity for engagement (personal resources), the groups' capacity for joint engagement (collective efficacy), and other stakeholders' willingness to engage. Seeing new possibilities to work together "with wise people," or identifying the potential engagement from other stakeholders, or feeling the internal strength and mandate to work toward the solution were all highly significant when explaining hope and motivation (as seen in Table 1). Equally, barriers to hope were explained as the lack of involvement from other stakeholders; lack of energy or stamina within oneself; or lack of power, mandate, or wisdom even, when working together. Depending on the context for the group, there were different concerns regarding stakeholders' involvement. In the case of the public service group (1), relevant stakeholders were already supporting the project, and in the Transition Sweden group (2), the group's approach did not depend on support from other stakeholders, although it still mattered to their endeavor. In the tenant groups (3 and 4), some of the participants felt disheartened about getting help from landlords, property owners, or the municipality. The interviews revealed individual patterns in how engagement affected levels of hope and motivation, independent of contextual differences. These differences are interesting, and clearly show that multiple factors are needed to explain these levels.

For some participants, their own engagement was used to explain their high level of hope and motivation, as in the following example: *"I have always lost. But that is not an issue, here, because there is no other way, anyway. What does it mean to be a realist? For me, it means to comprehend the possibilities of doing something differently"* (pre-interview, participant in group 2, with hope rate 7). This example connects to the concept of transformative hope (O´Hara, 2014), signifying the ability to feel hopeful about change and being motivated to engage even when faced with crises and continuous loss.

A combination of explanations was often used, sometimes clarifying why motivation was higher than hope in a participant: *"Engagement, that is not the problem whatsoever… I am not the only person that has been engaged in this. I think many people from here would engage if there were chances to change things. Many would engage to such end. There are several people who are tired of what we have here today"* (pre-interview, participant in group 3). This participant post-rated 1 on hope, but 7 on motivation, which showed that her own engagement was not significantly affected by her lack of hope, but she did not deem it possible to make much impact unless the system changed, involving decisions other stakeholders needed to make. Two participants from group 4 (tenants) stated that they had given up hoping that other stakeholders would contribute to improving conditions. From the viewpoint of these participants, the neighborhood was continuously deteriorating, and they were now thinking about moving. *"I am 100 percent motivated as long as I live here. All the time I do things; not just me. But one needs to hear some feedback. Otherwise, one does not have the strength to carry on. In the end, one gives up"* (post-interview, participant in group 4).

Another example relating to engagement shows how both hope and motivation vanished with lack of other stakeholder engagement: *"Right now I feel I have to let go of it. If nobody else cares, then I cannot sit here and shout about it"* (post-interview, participant in group 2). In three cases, participants (from groups 1, 2, and 4) contributed some of their hopefulness to a certainty that the issue would get worse (and hence more urgent to solve) and over time increase other stakeholders' motivation.

The examples above touch on the multidimensional relationships of hope and motivation and indicate that it may be hard to predict when hope and motivation will support public engagement. It is evident that factors that explain hope and motivation varied individually as well as contextually, but that stakeholder engagement positively affected hope, and group involvement was an essential factor for hope and motivation. This is in accordance with Ojala (2010), whose study showed that trust in other actors was both a constructive source of hope as well as a motivational force. When stakeholder engagement was perceived (or anticipated), this affected levels of hope and motivation positively, but several participants reported that they still were willing to engage, even beyond hoping for improvements. To explain this, Miceli and Castelfranchi's (2010) notion of "active hope" may be used, favoring action even in the face of a negative forecast and with low odds of success.

In the post-interviews, personal resources were mentioned neither as a source of hope nor as a barrier to hope. The category increased slightly as a barrier to motivation after participation. My interpretation as to why it was not mentioned as a source of hope after participation is that the participants were further along in the group process and had developed a reliance on the collective engagement, rather than emphasizing their individual resources. Reports from the interviews showed an increased confidence in developing action plans together with others: *"I noticed that it is possible to work in a group"* (post-interview, participant in group 2). The notion of collective hope is an important factor to consider, as seen in earlier research (Amnå, 2008; Nalkur, 2009; Ojala, 2011) and can be strengthened by a constructive group process (Ross, 2006). Through interactions with others, individual powers of agency can also be strengthen by gaining an increased stakeholder understanding (McGeer, 2004).

There were no indications of "passive hope" in my study, perhaps because all participants joined voluntarily, and joining the group meetings was already a mark of an active stance. But passivity did set in concerning parts of an issue that the participants had given up both hope of changing and motivation to work on, while they were still open to engaging where it made sense and seemed possible. In the cases when participants carried hope that others would make changes that were beyond the groups' resources or mandate, they were still motivated to engage personally, using the pathways that seemed available. The line between active and passive hope here appears to be strongly linked with pathway perception and estimated possibilities to affect the issue of concern (as with "authentic hope"), as well as the time and energy needed to do so. Consequently, the same person might be partially passive and lacking in hope and actively engaged and hopeful.

In this section I have attempted to show how levels of hope and motivation were affected by engagement in the issue of concern. For a fuller picture, a deeper investigation of how the relationship between individual, group, and other stakeholder engagement affects hope and motivation would be necessary.

Conclusions

Hope and Motivation as Dynamic Processes

Hope is sensitive to a variety of conditions, such as time, information, personal resources, social context, and perceived support. People's hope and motivation can be significantly strengthened when experiencing direct, personal ways of working productively in a group of participants that share an interest in solving common concerns (sense of collective efficacy). This sense of collective efficacy, together with support from other stakeholders, may be a central motivator for continuing with deliberation.

From a standpoint of working with TIP, the process offers ongoing, dynamic change, and when new information about the issue complexity begins to sink in, some frustration and lack of hope may surface, along with uncertainty about how to progress. It is my experience that later in the process—after a group has chosen a focus—hope tends to increase, especially when action strategies are considered that match the scope of the group and the complexity of the chosen issue. This study confirmed that the discovery of new potential pathways to manage the issue, through a more comprehensive understanding of the complexity involved, is a key factor for levels of hope and motivation, and hence, propensity to engage actively in efforts to address the issue.

As hope and motivation are continuously subject to dynamic change, the object of hope may shift over time, subjected to new conditions, such as access to new information and changes in social contexts. Moving away from “false (or naïve) hope” may at one point appear as lack of hope from a static viewpoint, but viewed dynamically, it may be the start of a renewed, different way of hoping. When facilitating groups, this may be important to keep in mind. If at one point, group participants experience lower levels of hope that desired outcomes are possible, it may be a phase of reduction of “false hope.” If the continued work leads to the discovery that at least parts of the issue complex may be successfully addressed, or that new, previously not thought of, pathways to solutions are discovered, new hope and motivation may arise.

To distinguish between generalized, particularized and transformative hope, may be important for understanding the dynamics of hope and motivation when dealing with issues of societal complexity. Before discovering the degree of complexity of an issue complex, hopes may be strong, because one does not yet have sufficient insight into the difficulties involved. But while increased awareness of complexity may lead to decreased hope regarding the possibilities of resolving the entire issue complex, a more differentiated understanding may lead to strongly increased hope that certain parts of the issue complex can be addressed successfully, even though other (perhaps major and important) parts will be more difficult to manage.

A tentative conclusion, gained from the study, is that reduced motivation is not necessarily a negative outcome of a group process, when working on complex issues. Participants may discover that the issue was not as urgent or important as initially thought. They might therefore have good reasons to engage less in that particular issue and instead prioritize other tasks in which it now seems relatively more important to engage.

A limitation of this study was that it is low in number of participants, which limits inferences from the findings. The significance of this research is first and foremost in drawing attention to the consideration that increased task complexity awareness – effected by a scaffolded issue analysis – may affect hope and motivation in complex ways. When working with groups, a dynamic and non-linear understanding of hope and motivation may enable a process facilitator to trace these kinds of changes.

Implications for Research and Practice

It is a challenge to scientifically investigate hope, to succeed in shaking off its epithet as a vague emotion (Ojala, 2011), while not creating a large gap between how researchers construct hope and what people really talk about when they talk about being hopeful (Bruininks & Malle, 2006).

In this study, some important findings were made, contributing to the understanding of the role of hope and motivation when groups work with complex issues of public concern. The main outcomes of the study were the following:

- an empirically based set of factors relevant for explaining patterns of change in hope and motivation when people participate in multi-phased processes designed to increase their ability to recognize, handle and potentially forsee task complexity
- empirical results regarding the dynamics between the factors and their level of importance for explaining hope and motivation.

While the constructs of hope and motivation have overlaps, the results showed that it might be highly meaningful to differentiate their meaning and explore how different aspects of hope relate to motivation to engage in action. Concrete examples of such relationships are offered through the distinctions made by the participants in the group processes. The study was limited in scope and more research would be needed to firmly grasp these dynamics.

How hope and motivation affect individuals, groups, and organizations when addressing complex public issues needs several research approaches to achieve a fuller picture of the roles that hope and motivation play. As mentioned earlier in this study, a deeper investigation of how the relationship between individual, group, and other stakeholder engagement affects hope and motivation is needed to understand these relational dynamics. Another perspective on this topic could prove valuable, namely, how various facilitators understand the dynamics of hope and motivation throughout group processes involving complex societal issues.

A natural progression from this study would be to investigate how increased hope and motivation affect deliberative decision-making on key issues, once groups have spent a significant time grappling with the issue complexity, using a scaffolding approach (such as TIP). This may entail community-wide questions, or policy questions within an institution. It would also be of value to study the dynamics between task complexity awareness and hope and motivation over longer time spans, while concurrently tracking how groups that grapple with issues of public concern over time transform their ways of dealing with these issues.

The main contribution was the uncovering of some of the complex dynamics between task complexity awareness, hope and motivation. This study indicated that increased task complexity awareness affect different aspects of hope and motivation in several ways. To understand these findings in more depth, further studies are required in order to gain more understanding about individuals' meaning-making processes. Such understanding can help inform facilitators who wish to actively mobilize the kind of constructive hope that can lead to purposeful and well-directed engagement.

Appendix 1. Modules of TIP used in each group

TIP modules that the groups carried out	Group 1	Group 2	Group 3	Group 4
Step 1: Create a map of the territory Identify all topics of concern and how they interconnect and impact each other. Use that work to inform the choice of one topic to start with.	✓	✓	✓	✓
Step 2: Align toward the goal Deliberate about how to use and coordinate people's different tones and intentions toward the work's focus.				
Step 3: Develop a portrait of the issue Identify the impacts and causes. Decide initial issue(s) to work on. Get a clear picture of the array of conditions that comprise the selected issue.	✓	✓	✓	
Step 4: Invent an action system Identify the array of changes to reactively and proactively impact the issue. Decide which can be done by an array of appropriate actors (e.g., individuals, groups, organizations, governments). Identify which ones represent discrete sub-issues.	✓	✓	✓	✓
Step 5: Use the action system and select a focus Review the list of potential actions and discuss what impacts the chosen scope of actions could have on the issue. Make decisions about appropriate directions forward individually, as well as for the group. Develop a statement of the goal for the group that communicates the chosen scope. *For a deliberative scope*: Articulate a precise issue question, or 'name,' for the sub-issue or complex decision that needs to be worked on and deliberated.	✓	✓	✓	✓
Step 6: Develop the approaches to the issue question Expose the array of approaches to the issue question that are driven by different perspectives on it.				
Step 7: Deliberative decision-making and meta-approaches Deliberate the pros and cons *within* each possible approach, and the pros and cons *across* all approaches. Make decisions about which elements of each approach are needed for a thorough, integral approach.				
Ongoing Step 8: Coordinate systemic action Divide into task groups, arrange oversight, develop and coordinate ongoing feedback and evaluation loops, etc.	✓	✓	✓	✓
Ongoing Step 9: Intentional systemic action, evaluation, and learning Engage in individual and institutional action, reflection, deliberation, evaluation, communication systems, adjustments, etc.	✓	✓	✓

Developing an Inclusive Perspective for a Diverse College: Inclusion = Diversity + Engagement

Cheryl Whitelaw[1]

Abstract: This article describes a project at the NorQuest College Center for Intercultural Education to develop an inclusion model for a post-secondary, two-year college. *Inclusion = Diversity + Engagement* is a model for action based on the integration of integral theory, particularly the all quadrants component of the *AQAL* model by Ken Wilber and the *Developmental Model of Intercultural Sensitivity* by Dr. Milton Bennett. The author views inclusion as a perspectival phenomenon, socially constructed; a culture of inclusion is, in part, founded on perspective seeking behaviors. Within the model, the focus for translative and transformative change is guided by the Intercultural Competence Stretch Goals document, a map created by the author and her project collaborators to identify selected attitudes, knowledge and skills to support more inclusive communication behaviors. The model is informed by concepts arising out of discourse on inclusion and intercultural competence, specifically on a capacity for perspective taking within a Canadian socio-cultural surround. Within the context of a college with identifiable diversity in terms of country of origin, languages spoken, race, ethnocultural origin including First Nations, Metis and Inuit peoples and the level of ability requiring supports (for physical and/or learning challenges), this article describes an organizational change project sparked by an applied research study to create the *Inclusion = Diversity + Engagement* model and the organizational change initiatives that flowed out of the model. The applied research question asked: “In what ways might Student Services enhance intercultural communication skills during face-to-face interactions with students.” We found a need to focus on the enhancement of intercultural communication skills based on a primarily ethnocentric, minimization worldview for student services staff. Specific skills included developing a deeper understanding of staff’s own worldview with a focus on identifying preferred communication styles and practicing less familiar, less comfortable styles. We also found a need to practice perspective taking to increase staff capability to check for inclusion in service interactions. Results were used to design inclusion training; the project evolved to develop an integrally informed inclusion map. These organizational change initiatives are continuing through an ongoing

---

Introduction Developing an Inclusive Perspective for a Diverse College: Inclusion = Diversity + Engagement

This article describes a change initiative to foundationally anchor inclusion as a lived organizational value in a 2-year community college. The engine for organizational change was tuned through an initial applied research study, an initial inclusion training intervention and the development of a model for action; this model has become a guiding map for inclusion based on an integration of the AQAL model from integral theory (Wilber, 2000a) and a developmental model of intercultural competence (Bennett, 1986). The article describes the context for the project overall including the conceptual landscape the Inclusion = Diversity + Engagement model rests upon, the applied research study, and the situation-specific interventions and results at NorQuest College to embed inclusion as a core value for the organization. The applied research project used a mixed-methods research design focused on a specific section of the College; the Student Services teams. This focus was selected by taking the perspective of NorQuest students; their first experience of the College and their experience of inclusion (or exclusion) occur through interactions with Student Services staff. The question posed for the study was, “It what ways might Student Services enhance intercultural communication skills during face-to-face interactions with students?” Results from the research informed a specific approach to inclusion training for student services staff and were shared with Student Services leadership. After initial piloting and evaluation of this inclusion training, a more encompassing Inclusion model was developed and has since been applied across the organization.

Inclusion has been an abiding question in a two-year community college with a 50 year history of serving a diverse student population. As a learner-centered College with visible services and facilities to accommodate and adapt to the diverse needs of the learners who attend, this is an institutional performance benchmark with heart. What is inclusion? What does it look like? How do we understand and learn from the perspectives of inclusion and exclusion? How do we know how we are doing? Do our systems and environments support or deter inclusion? This project tapped a deep-seated desire to engage and empower the diverse adult learners at the college. That essential value was catalyzed into an ongoing inclusion initiative. The initiative and the organization are still evolving. Inclusion is a lived value at NorQuest College.

---

[2] For the model development, I want to thank Kerry Louw, Center for Intercultural Education, NorQuest College and Meg Salter from MegaSpace Consulting for their willingness in the Inclusive Student Engagement project to grind through the work of combining two theoretical models to reach the simplicity of integration that comes on the other side of that complexity. For a complete listing of collaborators and participants, see the Acknowledgements page in the Inclusive Student Engagement Final Report at http://www.norquest.ca/NorquestCollege/media/pdf/centres/intercultural/ISE/ISEFinalReport_Nov2012.pdf.

Definition of Terms

Several terms are used in the article. Although discussed in greater detail throughout the paper, these terms for the purposes of the Inclusion = Diversity + Engagement project are defined here.

Inclusion is defined as a sense of belonging, having the ability to participate in the social, economic and political lives of one's communities and having all contributions to the community acknowledged. The focus in our Inclusion model was to set up the environment to be a fully participatory, socially constructed reality with demonstrable public characteristics and associated meaning or values. It is defined as a co-created reality, rather than a dominant group member allowing participation by marginalized group members.

Developmental Model of Intercultural Sensitivity (DMIS) by Dr. Milton Bennett describes intercultural competence as a developmental continuum of increasing capacity to perceive, accept and adapt to similarities and differences in the cultural worldviews we encounter. The intercultural continuum identifies clustered of cultural worldviews from ethnocentric (perceiving and understanding the world through one's one cultural worldview) to increasingly ethnorelative (perceiving and understanding the world through more than one cultural worldview).

Diversity is defined as any visible or invisible socially salient identity held by an individual. Categories of diversity can include race, ethnic origin, identity as a First Nations, Metis or Inuit person, people with disabilities, gender, sexual orientation, etc.

Intercultural Competence is defined as the appropriate and effective management of interaction between people, who to some degree or another, represent different or divergent affective, cognitive, and behavioral orientations to the world. These orientations will most commonly be reflected in such normative categories as nationality, race, ethnicity, tribe, religion or region…the extent to which individuals manifest aspects of, or are influenced by, their group or cultural affiliations and characteristics is what makes an interaction an intercultural process (Spitzberg & Changnon, 2009). In intercultural experiences, we typically create meaning using sets of categories based on our experiences within our own cultural worldview to organize our perception of observable facts.

Intercultural Developmental Inventory (IDI) is a validated psychometric tool designed to measure the orientations toward cultural differences described in the DMIS. The current version of the IDI is a 50 item questionnaire with 10 demographic questions (Hammer 2003).

Intercultural Knowledge and Competence Value Rubric is a rubric identifying 6 core characteristics for intercultural competence developed by the Association of American Colleges and Universities in 2006. The rubric describes the skill, knowledge and attitude at each stage in the intercultural continuum as described the DMIS (Association of American Colleges and Universities, 2006).

Perspective taking is defined as the developing capacity of a subject to become aware of and consequently take or seek the perspective of a real or hypothesized individual or group with the intent to use the information about the object dimension enacted for some instrumental purpose (Fuhs, 2013).

Quadrants: In the AQAL model, the four quadrants can be used as dimension of phenomenon or perspectives. Using the quadrants, an individual can look at the dimensions of reality (e.g. experiential, behavioral, cultural and social/systemic).

Quadrivia refers to four ways of seeing or perspectives. Quadrivia express the simple recognition that everything can be viewed from two fundamental distinctions: 1) an inside and an outside perspective and 2) from a singular and plural perspective.

An extension of these definitions of basic dimensions and perspectives of reality is the application of the quadrants/quadrivia in two specific ways. First, to look at the functionality in each quadrant (inside/outside; singular/plural) or “Looking At” (Divine, 2009). In this project we looked at the dimensions of inclusion from an organizational level of analysis. Second, to discern ways of orienting from each perspective or “Looking As” (Divine, 2009). In this project we also attempted to occupy the perspective of inclusion from a student service staff (and to a lesser extent, student) orientation. This “Look At” and “Look As” frame for perspective taking was also applied as a way to facilitate perspective seeking exercises in the Photo Voice project as part of the inclusion training. Briefly participants engaged with photos of inclusive (or exclusive) subjects (Looking At the photos) and with the photographer’s perspective of the photo (Looking As the photographer). The author acknowledges that the linkages between these definitions and uses in our project do not fully represent the theoretical intent and context of use in Wilber and Divine’s work. The application of a relatively simplified version of quadrants and quadrivia/Look At and Look As were helpful to facilitate an enlarged concept of perspective taking in the inclusion organizational change project.

Conceptual Model 1: Intercultural Competence for Inclusion

What is inclusion? Operationally at NorQuest, inclusion has been understood and acted upon as a focus to reduce barriers for adult learners to participate in education with the aspiration of supporting student success. Student success has been striven for in both institutional (program completion, learner retention) and individual terms (student satisfaction with learning experience, completion of learner goals).

Social inclusion is derived from social policy contexts in Europe in the 1970 - 80s as a counterpoint to the phenomenon of social exclusion, what was viewed as primarily an economic marginalization of members of society who do not cohere to societal norms. Social inclusion (and exclusion) implies a coherent society in which members are included or marginalized. A sense of solidarity is described first by Durkheim (1933) as a relatively mechanistic concept of society reproducing itself due to general consent to follow social rules grounded in perceived truths. Institutions in society uphold accepted truths including formal prescriptions of work and education as well as associations, religious groups, clubs and unions (Durkheim in Giddens, 1971). In Canada, more of a social integrationist perspective prevails (over a Durkheimian one espousing social stratification), a perspective valuing multiple points of identity in the construction of the social sphere (Wilson, 2006). Within this perspective of social inclusion, NorQuest is an institution that upholds societal rules and develops members to contribute to society.

As our project is grounded within a societal container, it is appropriate to explore how social inclusion is understood within the surround of a Canadian societal context. Social inclusion was recently defined in Canada as an evolving concept, in which individuals or groups of individuals are able to participate in the social and economic lives of their communities and have their contributions acknowledged (Senate Canada, 2013). Within this evolving pluralistic society, social cohesion becomes more dynamic, an ongoing process of developing a “community of shared values, shared challenges and equal opportunity within Canada, based on a sense of trust, hope and reciprocity among all Canadians” (Jenson, 2003, p. 4). However in the pursuit of shared values, tolerances become stretched for people perceived as difficult to include (Young, 1999). As a diverse college, our socializing institution is a place where conflict can and does arise, when diverse people engage closely together. A concern for social inclusion emerges out of the very real challenge of getting along within the shared educational environment.

Several concepts are used to illuminate what social inclusion actually is. Concepts for social inclusion include solidarity (the cohesion based on similarities among people and shared rituals and routines and the emotional bonds created through collective activities) (Wilson, 2006); social cohesion (a process that ensures every individual has the opportunity to meet their basic needs, access to rights and protections and to dignity and self-confidence (Council of Europe, 2001); and social capital including the in-group reciprocity of shared resources (bounding) and social networks that engage reciprocity across diverse peoples (bridging) (Putnam 2000). Social inclusion is complicated by intersectionality, the possibility that “an individual may experience multiple dimensions of difference that could reinforce his or her social exclusion and as a result intensify the challenge of facilitating her or his inclusion” (Senate Canada, 2013, p. 8). The social cohesion necessary for inclusion seems to be construed as both structural; achieved through the patterns and structures of economic mechanisms related to the relative experience of prosperity and collective choices and goals facilitated in Canada most often by government and public institutions, and personal; the values and behaviors of society members that contribute to perceived conditions of order, stability and cohesion (Jenson, 2002). Jenson argues that social cohesion is derived through how a society addresses its diversity, how it invests in processes to manage inevitable conflicts arising within a diverse society, to maintain a capacity to be open and permeable to diverse interests. She identifies that in Canada cultural policy is used as a way to “manage the relationship between diversity and social cohesion” (Jenson, 2002, p. 5). From this policy stance, maintaining a diverse and socially cohesive society is possible through well-managed socioeconomic conflicts.

Bringing this concept of social inclusion back to the ground of a postsecondary institution tasked with facilitating the development of our learners to become fully participating members of society, how can this kind of social inclusion be enacted? We sought to change the conversation of inclusion among all College community members, starting with student services staff and to a certain extent with students. Intergroup dialogues for students have been an ongoing movement in American universities. Intergroup dialogues bring learners together from two or more social identity groups to talk about important social issues in substantive ways. Participants in dialogues are facilitated to safely practice listening, to ask questions of others and to commit to understanding the perspective of others (Gurin, Nagda & Sorensen, 2011). Psychological changes in attitude and worldview are a strong focus of attention by intergroup dialogue practitioners and theorists. Empathy building (Batson, Chang, Orr, & Rowland, 2002), critical self-reflection and perspective taking (Gurin, Nagda, & Lopez, 2004) and reduction of perceived threat to interaction between dominant and marginalized groups (Comerford, 2003) are cited through several studies as inclusionary outcomes of intergroup dialogue in American contexts. In the student-oriented inclusion activities that emerged as part of the larger organizational change initiative, we used conversation circles or inclusion circles as part of the Inclusion Fusion event, open to the whole college community and engaged students to be circle hosts. Circle agreements upheld many of the factors identified by intergroup dialogue practitioners.

At the NorQuest Center for Intercultural Education, we began to explore inclusion as a "socially constructed reality" (Ford, 1999, p. 480). Ford describes first-order realities, the "physically demonstrable and public discernible characteristics, qualities, or attributes of a thing, event, or situation," and second order realities, as "created whenever we attribute, attach, or give meaning, significance, or value to a first-order reality" (Ford, 1999, pp. 481-482). The consequences of this meaning-making activity can create "concrete results of a personal and societal nature…First and second-order realities are rarely constructed solely by direct personal experience, but are inherited in the conversational backgrounds (e.g. cultures, traditions, and institutions) in which we are socialized…Socialization gives us instructions on how to see the world, and we operate as if the world really is that way" (Ford, 1999, p. 482-483). Seeking to build on demonstrable and visible components of inclusion (ie. programs and services targeting learners with specific needs), we focused on conversations as a way to nurture an existing culture of inclusion, not solely from a top-down or special interest group agenda but as a co-created one, a conversation in which everyone is welcome to contribute their voice and perspectives. This conception of inclusion was the sole one used in our project as it aligned well with our espoused approach to intercultural competence, one that focuses on the communication interaction between people.

Inclusion as an Expression of Intercultural Competence

Inclusion is the outcome we sought; cultivating intercultural competence was the skillful means we chose to achieve it. At the Centre, we seek to promote intercultural competence in Canada through applied research, training and education using a developmental model of intercultural competence. Although many definitions of intercultural competence exist, one that captures key salient points is included here, "intercultural competence is the appropriate and effective management of interaction between people, who to some degree or another, represent different or divergent affective, cognitive, and behavioral orientations to the world. These orientations will most commonly be reflected in such normative categories as nationality, race, ethnicity, tribe, religion or region…the extent to which individuals manifest aspects of, or are influenced by, their group or cultural affiliations and characteristics is what makes an interaction an intercultural process" (Spitzberg & Changnon, 2009, p. 7). The Centre's focus for intercultural competence, and for inclusion, is within the interaction space between people, on growing the mind, heart and skill sets to engage others through the lens of this competence.

The Developmental Model of Intercultural Sensitivity

The theoretical tool we used to develop intercultural competence is the Developmental Model of Intercultural Sensitivity or DMIS (Bennett, 1993). The DMIS describes intercultural competence as a developmental continuum of increasing capacity to perceive, accept and adapt to similarities and differences in the cultural worldviews we encounter. In this theory, cross-cultural experiences are constructed ones; we typically create meaning using sets of categories based on our experiences within our own cultural worldview to organize our perception of observable facts. Our categories influence our perspective, how we create our second order reality. Robert Kegan notes, “the failure to take responsibility for the invented nature of our meaning-constructions when these constructions are regulated by culture is in fact the essence of ethnocentrism” (Kegan, 1994, p. 206). We understand the world we experience through our conscious and unconscious biases, formed through our earliest development within our native cultural environment. Through developmental work, we can become conscious of how we use our culturally informed categories to make meaning; recent work on unconscious bias provides ample evidence that we are subject to our unconscious bias as well (Banaji & Greenwald, 2013).

In the DMIS theory, the developmental continuum describes stages of cognitive complexity and the behaviors arising from our cognitive capacity, ranging from a mono-cultural or ethnocentric mindset, (the capacity to explain and interact with similarities and differences from our own, familiar cultural worldview) to an ethno-relative or intercultural mindset, (the capacity to explain and interact with similarities and differences within more than one cultural worldview).

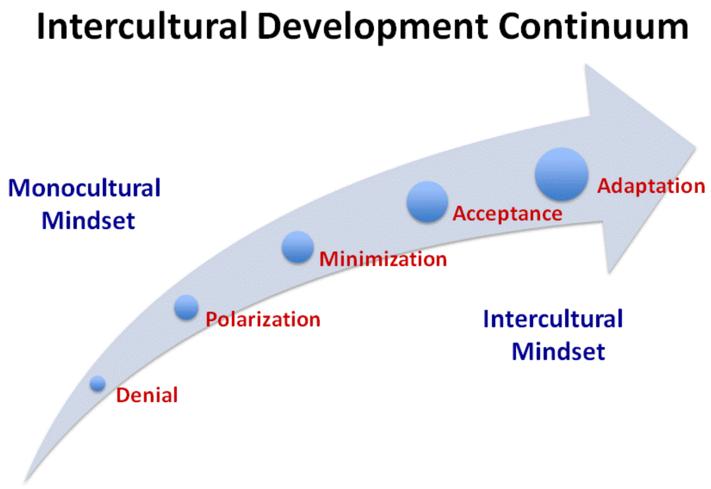

Figure 1. Developmental Model for Intercultural Sensitivity – Intercultural Development Continuum (adapted from Hammer, Bennett & Wiseman, 2003).

In this model, developing intercultural competence is creating an increasingly complex capacity to perceive similarities and differences, to accept those as part of a dynamic and complex worldview. Hammer, Bennett & Wisemen (2003) define intercultural sensitivity as “the ability to discriminate and experience relevant cultural differences" and intercultural competence as "the ability to think and act in interculturally appropriate ways." The authors posit that greater intercultural sensitivity is associated with greater potential for "exercising intercultural competence." (p. 422) Bennett notes "the extent to which the event of cultural difference will be experienced is a function of how complexly it can be construed." (Hammer, Bennett, & Wiseman, 2003, p. 423).

Each orientation described on the DMIS is a cluster of self-reported attitudes and behaviors indicative of the underlying worldview.

> Each change in worldview structure generates new and more sophisticated issues to be resolved in intercultural encounters. The resolution of the relevant issues activates the emergence of the next orientation. Since issues may not be totally resolved, movement may be incomplete and one's experience of difference diffused across more than one worldview. However, movement through the orientations is posited to be unidirectional, with only occasional ''retreats.''
>
> In other words, people do not generally regress from more complex to less complex experiences of cultural difference. (Hammer, Bennett, & Wiseman, 2003, p. 423)

The first three orientations, moving left to right on the Intercultural Development Continuum, describe orientations that can be categorized as ethnocentric cultural worldviews; the experience of cultural differences is made sense of primarily through one's own cultural context. The DMIS described orientations include Denial, a state in which one's own culture is the only one experienced as real. People with a Denial worldview are generally disinterested in cultural difference or experience it as an undifferentiated other such as a foreigner. The next stage, Defense is a state in which one's own culture is experienced as the only possible one. People with a Defense worldview can discriminate cultural differences at a stereotypical level. At this stage, people are more openly threatened by cultural differences…the worldview places experience of differences into a category of either "us" or "them" where one's own culture is superior and other cultures are inferior. A variation of Defence is Reversal, where the other culture is viewed as superior to one's own culture, while maintaining a polarized "us" and "them" worldview. A Minimization orientation is a state in which one's own cultural worldview is experienced as universal; perceived differences are subsumed into similarities (e.g. we all have red blood). At this worldview, people expect similarities and may correct others' behavior to match their expectations. When occupied from a place of dominant culture in a society, this worldview can mask recognition of the privilege afforded to members of their own culture.

The second three orientations are categorized as ethnorelative, meaning one's experience of culture references other cultural contexts. Acceptance is a state in which one's culture is accepted as one of many worldviews. From this worldview, people can use cultural pattern categories that allow them to contrast different cultural worldviews. Acceptance does not mean agreement. The challenge at this stage is to discover how to maintain ethical commitment in the face of the relativity of values across cultural worldviews. Adaption is a state in which "the experience of another culture yields perception and behavior appropriate to that culture" (Hammer, Bennett, & Wiseman, 2003, p. 425). People at an Adaptation stage can take perspectives, meaning to be able to shift their frame of reference and express feelings and behaviors in ways that are deemed culturally appropriate in more than one cultural context. Adaptation could be expressed as a biculturality or multiculturality if the process of shifting frames is deepened and embodied. The final stage, Integration, (not shown on the figure 1 Intercultural Development Continuum) is described as a state in which "one's experience of self is expanded to include the movement in and out of different cultural worldviews." (Hammer, Bennett, & Wiseman, 2003, p. 425). In this stage, people construe their identities at the margins of two or more cultures which can be experienced as alienation or in a constructive form. Integration does not necessarily include greater intercultural competence than the Adaptation stage; it does include a description of the identity of people who experience cultural and physical mobility, including long-term expatriates and global nomads.

In our research, we understood the developmental task for our student services staff group was to change the conversation. We needed our intervention to begin a shift from a perspective-maintaining Minimization stance that espouses sharing of universal experiences to a conversation that is open to learning about and engaging differences that may be uncomfortable to include from within this stance. We did not hold specific views about how much or how far along the continuum people should travel. We simply wanted to hold open the space for the development that was possible, to hold space for it to happen as it would happen. We believe the combination of this focused intent and openness to outcomes is a necessary condition of safety for participants to enter into a potentially uncomfortable, potentially worldview threatening learning space.

Intercultural Development Inventory: Measuring Intercultural Competence

The DMIS theoretical model is supported by a tool, The Intercultural Development Inventory (IDI). The IDI is a validated psychometric tool designed to measure the orientations toward cultural differences described in the DMIS. The current version of the IDI is a 50 item questionnaire with 10 demographic questions. Inventory items reflective of the Denial and Defence stages include: "(1) It is appropriate that people do not care what happens outside their country, (2) People should avoid individuals from other cultures who behave differently, and (3) Our culture's way of life should be a model for the rest of the world". Sample items from the Minimization stages include: "(1) Our common humanity deserves more attention than culture difference, (2) Cultural differences are less important than the fact that people have the same needs, interests and goals in life, and (3) Human behavior worldwide should be governed by natural and universal ideas of right and wrong." Items from the Acceptance and Adaptation scale include "(1) I have observed many instances of misunderstanding due to cultural differences in gesturing or eye contact, (2) I evaluate situations in my own culture based on my experiences and knowledge of other cultures, and (3) when I come in contact with people from a different culture, I find I change my behavior to adapt to theirs" (Hammer, Bennett & Wise, 2003, p. 246).

Initial testing of the IDI focused on ensuring the systematic re-creation of the empirical observations that the DMIS is based upon. The construct validity of the IDI was tested through relating the stages to two theoretically related variables, Worldmindedness, an assessment of international attitudes (Sampson & Smith, 1957) and Intercultural Anxiety (adapted from the

Society Anxiety scale by Stephen and Stephen 1985). The Intercultural Anxiety scale focuses on the "degree of anxiety respondents experience when interacting with people from cultures different than their own" (Hammer, Bennett & Wise, 2003, p. 246). The scale identifies a range of responses including feeling more or less overall anxiety, described by respondents as feeling comfortable, accepted, irritated, awkward, impatient, defensive, suspicious, self-conscious, careful, and nervous. Hammer, Bennett & Wise note that, "a number of studies have found this measure to maintain satisfactory reliabilities across cultural contexts (e.g., Gao & Gudykunst, 1990; Gudykunst, 1989; Hammer, Wiseman, Rasmussen, & Bruschke, 1998)" (p. 437). The validation results confirmed the proposed relationships among the IDI scales and these two theoretical models. Higher scores for a Denial and Defense orientation as measured by the IDI are related to less Worldmindedness and greater Intercultural Anxiety. Higher scores for an Acceptance and Adaptation orientation in the IDI scale is significantly related to more Worldmindedness and decreased Intercultural Anxiety. "Additional testing done on these five scales on gender, age, education level, and social desirability reveals no significant effects by age, education level, or social desirability and no significant effects on four of the five scales by gender" (Hammer, Bennett, & Wise, 2003, p. 439).[3]

Future work on the current IDI inventory suggested by Hammer, Bennett & Wise relates to the accuracy of the developmental sequence from Denial/Defense to Minimization to Acceptance/Adaptation worldviews and the predictive validity of higher IDI scores associated with a more ethnorelativistic worldview related to conditions such as "more satisfaction with living/working in a foreign culture", "greater job accomplishment in culturally different environments" and "less resistance to diversity initiatives in organizations" (Hammer, Bennett & Wise, 2003, p. 441). In our study, we have preliminary findings that link a more ethnorelative worldview with greater capacity for inclusive student services. More work is needed to replicate that assertion and to expand it to apply to inclusive faculty-student interactions.

In our study, the IDI was an important tool to use as a lens to focus our work. It afforded us the discernment to calibrate training to a learning edge for the majority of our training participants (within the Minimization stage) and through facilitation, to acknowledge and ground the experiences of participants orienting from other stages in the DMIS. Part of learning how to honor people and what they bring was the lesson of holding this lens lightly, as a tool to reflect on self and others and to illuminate experiences of similarities and differences to question and explore. Through its nature as an inventory, it provides a tool to Look At stages of intercultural sensitivity. In its application, it is equally important to engage with the tool as a way to take perspectives, to Look As different stages of intercultural sensitivity, to acknowledge and honor the learning and development journey from any point along the intercultural continuum.

Comparing Theoretical Lenses – One Phenomenon; Many Theories

Intercultural competence is a phenomenon that multiple theoretical models have been proposed to illuminate its interior (competence as a function of thinking, emotions, beliefs, attitudes, values, additive cultural norms) and exterior (competence as a function of behavior, interpersonal and intrapersonal, organizational processes and environments) qualities. Models of intercultural competence can be typologies or lists of traits, characteristics and skills that are proposed to be part of competent interaction. They can also be co-orientational models, focusing on outcomes, namely, the interactional achievement of mutuality and shared meaning through communication. Developmental models, like the DMIS, are focused on stages of progression over time. Adaptational models focus on interdependence and mutual adjustment of participants in an interaction. One challenge for each model type is to create clarity on what is intercultural competence, what levels of proficiency are needed, what specific combination of criteria or outcomes determines competence (Spitzberg & Changnon, 2009).

---

[3] Detailed procedures related to the psychometric testing process of the IDI are contained in the article by Hammer, Bennett & Wise.

Given the complexity of intercultural competence as a phenomenon, studies using different theoretical lenses within diverse contexts and with diverse audiences brings different facets of this competence into focus. One context is the field of international education and the early stage adult development of post-secondary students. An example of a typology model, the Process Model of Intercultural Competence by Dr. Darla Deardorff is situated in studies of intercultural competence as an outcome of international education in postsecondary education institutions in the United States. Deardorff used a Delphi method to seek consensus among college administrators and intercultural scholars on lists of components for intercultural competence; 80% of participants were able to reach consensus on 22 elements of intercultural competence. Highlights of the items include flexibility, tolerating and engaging ambiguity, deep knowledge and understanding of culture (one’s own and others), understanding the role and impact of culture and of situational, social, and historical contexts involved, withholding judgement, mindfulness and learning through interaction.

Deardorff focuses on representing these primarily cognitive components in a process model of intercultural competence. This model outlines the process of acquiring intercultural competence beginning with individual attitudes (e.g. respect, openness, curiosity & discovery), moving to acquiring knowledge & comprehension of cultural self-awareness, deep cultural knowledge, sociolinguistic awareness and acquiring skills (e.g. the ability to listen, observe & evaluate, to analyze, interpret and relate). In her model, she allows that there can be both internal and external outcomes when individuals engage in intercultural interactions. Desired internal outcomes include an informed frame of reference shift, characterized by adaptability, flexibility, an ethnorelative view and empathy. Desired external outcomes include effective and appropriate communication & behavior in an intercultural situation. Deardorff’s model points to rather than explicitly articulating developmental progress with ongoing application of the process. “The degree of intercultural competence depends on acquired degree of attitudes, knowledge/comprehension and skills” (Deardorff, 2006, p. 256). In this model, the focus is on the process of acquiring intercultural competence illuminating individual competence characteristics and an interplay between internal and external competence acquisition. As a typology model, it is easy to apply to educational settings; it is less clear how to determine markers of progress in the process of acquiring intercultural competence. Deardorff’s model influenced the inclusion training activities developed. Behavioral skills are a key focus in the training with facilitated reflections linking participants’ experiences to intercultural competencies and developmental learning goals.

Kupka's Intercultural Competence Model for Strategic Human Resource Management (Kupka, 2008) is an example of an outcome-focused, co-orientational model focused on three specific outcomes criteria including impressions of appropriateness and effectiveness, awareness and agreement on diverse meaning systems, and mutual relationship satisfaction. A core focus for this model is the achievement of "some minimal level of common reference through interaction" (Spitzberg & Changnon, 2009, p. 20). In this focus on intercultural competence as pathway to mutual understanding, the intercultural interaction is described as the interactions of the perceptual world (called intercultural perceptas) of each person through the process of communication, generating levels of overlap in shared symbol systems (called intercultural conceptas) leading to levels of mutual understanding. These interactions for mutual understanding take places in various contextual fields called noise (e.g. environments, situations, semantic, physiological and psychological). Typically co-orientational models take in more factors of the surround for intercultural interaction and the acknowledgement that this interactional space holds the potentiality for these interactions to become the cultural surround themselves. This focus is less readily applicable to the behavior of individuals participating in the interactions, contributing to the cultural surround. While more complete in describing the context for intercultural competence, we found Kupka's model difficult to put into action. Combining Deardorff's process model with the DMIS, we found we had a way to hold a focus on practicing specific behaviors and attitudes within a developmental framework.

Perspective Taking – What is Includable? A Core Intercultural Competence for Inclusion

Interculturally competent people are adept at and have the capacity to engage in perspective-taking, to look at their own assumptions and categories of interpretation as well as those of other people. The capacity to look at one's own perspective creates the spaciousness, the possibility to choose how to act on the information generated from these sense-making processes. The heart of this developmental approach is the observation that a sufficient capacity to take perspectives – to understand and engage with what is unfamiliar to us is core to positively engage people with differing worldviews. Kegan notes, "A friendly naiveté becomes ugly because if someone is includable, it is because his difference can be translated to what we take to be real, and if his difference cannot be so translated, he is not includable." (Kegan, 1994, p. 208). This capacity to look at our own meaning-making categories and behaviors arising from our interpretative frameworks was a core goal for the *Inclusion = Diversity + Engagement* model and the inclusion-promoting activities arising out of the model.

(inclusion)
= DIVERSITY + ENGAGEMENT

Figure 2. Inclusion = Diversity + Engagement model for action

In the context of inclusion at a college, a key precept for the *Inclusion = Diversity + Engagement* model is that inclusion is a perspectival phenomenon, socially constructed by the people engaged in interactions within the institution. Fuhs' definition of perspective-taking provides both clarity and utility. He describes perspective taking as, "the developing capacity of a subject to become aware of and consequently take or seek the perspective of a real or hypothesized individual or group with the intent to use the information about the object dimension enacted for some instrumental purpose" (Fuhs, 2013, p. 8).

In the context of a student service interaction, inclusion and perspective-taking action is bounded by the service goal, the context and potential constraints of the service context (e.g. rules related to student funding, time constraints for each front-line service interaction, etc.). We wanted to ensure that perspective-taking within an inclusive student service interaction was anchored to the goals of the service provided or requested, the context of the service as well as the cultural characteristics of the staff and students participating in a service interaction. Our operating hypothesis was that inclusion in this service interaction becomes more possible when the shared capacity of college community members is situated within or developing towards an ethnorelative mindset.

Barriers to Perspective Taking

Following one of the implications of a developmental model of intercultural sensitivity to enact a more inclusive organizational culture, what barriers exist at a predominantly ethnocentric worldview to take the perspective of another? If the ability to perceive difference is primarily framed through the lens of what is familiar, the information available to a person, with positive inclusion intent and goals, will be necessarily limited to the degree of difference that can be perceived and included from their stage of development (as defined by the DMIS). Fuhs discusses the factors that affect accuracy in perspective taking, the sources of information about a person (e.g. "dress, facial expression, movement, voice quality, and verbal statements,…past experience with the [person],…, subject's perceived self-similarity to target,….perceived in-group similarity and out group stereotypes;…and other people's perspectives regarding the target" as well as information about the context that "influences expectancies" (Fuhs, p. 17, 2013). He notes that limits to perspectival accuracy can also be shaped by "task demands, attentional constraints, and egocentrism may prevent accessible information from being selected as relevant" (Fuhs, 2013, p. 17). "Because one's own perspective tends to come to mind more rapidly, readily, and reliably than information about others' perspectives, one's own point of view may tend to serve as the default perspective for interpreting the world (Krueger, 1998 cited in Epley & Caruso, 2009, p. 300).

Perspective taking requires work; to overcome our own egocentric experiences, to seek information that accurately relates to another's perspective and not simply a projection of our own requires significantly more effort than mining our self-centric experiences to reach judgements about another's perspective (Epley and Caruso, 2009). We saw this acknowledged by our inclusion training participants through their reflective assessment assignments; several participants identified increased awareness; fewer commented on the effort and sustained focus needed to change service practices. In the inclusion training and other interventions designed to enhanced inclusion within the College, training activities included the work of perspective taking practices to build this muscle.

Perspective Taking to Perspective Seeking

In nurturing a culture of inclusion and building shared competencies to engage positively across cultural and other differences, we identified the need to situate interventions beyond a cognitive perspective taking exercise to a more embodied experience. Within the inclusion training and in other organizational activities guided by the *Inclusion = Diversity + Engagement* model, we focused on creating intercultural spaces to give both permission and opportunity for “perspective-seeking” activities (Fuhs, 2013, p. 20). To focus more accurately on the knowledge, skills and attitudes for the practice of a more embodied perspective-seeking, we created a framework, the Intercultural Competence Stretch Goals framework, to better identify the developing edge of core intercultural competence for each stage described in the DMIS. The Stretch Goals document is based on the 6 core characteristics for intercultural competence in *the Intercultural Knowledge and Competence Value Rubric* (Association of American Colleges and Universities, 2006), describing the skill, knowledge and attitude at each stage in the intercultural continuum as described the DMIS. For example, in describing the attitude of openness, we emphasized the demonstration of openness by how we work with our judgements, attending to the link between judgements and behavior within an interaction.

Given the evidence a majority of our audience occupied a worldview associated with the minimization stage of the DMIS, we refined our focus for intercultural competence development by clarifying the developmental edge for people at this stage. We proposed that a person oriented from this worldview is open to interactions with culturally different others, yet may have difficult suspending their own judgment. This person is beginning to see their own perspective as a perspective and tends to view much of their perspective as superior or correct. Within this orientation, a person may be willing to review and change some of his or her judgments and may be willing to examine cultural patterns as the basis for their own behaviour. The stretch goals for a person from this orientation is beginning to suspend their own judgements, refrain from stereotypical responses and ask questions from a stance of open curiosity to establish a deeper level of connection with another person. The stretch goals also include a growing recognition that other cultures have different views and ways of communicating. As a stretch goal, a person in this orientation may begin to attempt to shift their own communication style in certain contexts to better understand their own perspective and increase their ability to notice other communication styles.

One of the key insights in developing the stretch goals was how, generally, in our training practice, we had been engaging our learners from our own developmental perspective, our own edge. By making visible the stretch goals at each stage, we realized that we had to honor and meet our learners just in front of their stage, to align with their perspective and engage them just a little bit more, to elicit the beginning of what potentially is a transformative learning experience. For this kind of developmental movement, changing behavior can be one way to enable transformative development with an underlying process of learning and reflection to make sense of experiments in behavioral change (Deardorff, 2006). I suggest that adding communication styles without a sense making, frame-shifting reflection process is more likely to result in a translative development, increasing the set of communication competencies without necessarily changing perspective-taking capacity overall. Based on participant responses to reflective assessments and end of training surveys, more participants made comments of learning that align with translative development (e.g. learned to use more communication styles) than made comments aligned with transformative development. (e.g. recognition it is possible to accept a different perspective without needing to change or impose own perspective).

This overview of some of current theoretical approaches to intercultural competence registers the challenge to account for a multi-faceted phenomenon, particularly how to take informed action from more than a partial perspective. The very perspective occupied by the theorist articulates a partial and illuminating view of the whole. In the project, we were drawn to create bridging documents like the Intercultural Competence Stretch Goals framework to enable informed action. Rather than bringing on yet another definition or concept, the AQAL model brings a promise of wholeness, a way to frame and engage with the many aspects of intercultural competence and inclusion all at once. The following section will describe the applied research project. Next the author describes the process to create the Inclusion = Diversity + Engagement model with a focus on the second conceptual piece of our model for action, the all quadrants part of the *AQAL* model from integral theory.

Changing the Conversation of Inclusion - Applied Research Methods

Inclusion in Context: Student Services

To begin a different conversation for inclusion, we choose the student service interaction as a focus for intervention, for study and the container for the conversation of inclusion (and exclusion). This choice for an inclusion study built on the existing institutional culture of student services to remove barriers for students. Student services at the college include information services (offered in person, by phone and online), registration services, financial aid services, academic, career and personal counselling services (including services offered by Aboriginal staff and through an Aboriginal worldview), assessment services (many of our students require language or academic assessments to establish their pre-requisites to enter either upgrading or post-secondary programming), and a full range of disability-related services from assessment to assistive technology and learning strategy supports. This array of welcoming and retention-related student services is one of the primary ways students engage with the College outside of their program of studies (i.e. student engagement with faculty, clinical practicum staff, etc. was not included in the focus of our study). An applied research project was created to both better understand the context of student services, service practices that already include inclusive characteristics, and challenges to service provision related to perceived inclusion (or exclusion) of students. The research question posed was “In what ways might Student Services enhance intercultural communication skills during face-to-face interactions with students.” Two sub-questions were also posed, “How do NorQuest students and staff perceive current student service interactions at NorQuest?” and “How can IDI guided (Intercultural Development Inventory) training and coaching interventions be used to create inclusive student engagement interactions at NorQuest College.” Our hypothesis is that the development of intercultural competence (as defined by the Developmental Model of Intercultural Sensitivity) for Students Services staff will support positive, inclusive interactions between Student Services staff with diverse students. We hypothesize that by supporting staff to become aware of their interpretation of the meaning of differences they encounter in the context of a student service interaction, we can create the opportunity for choice on how to respond to those differences. Data collection activities included initial focus groups with front-line service staff, observations of student service interactions, and pre-inclusion training IDI inventories for participating student services staff. Post-inclusion training IDI inventories were collected to assess intercultural competence changes. Post-training exit surveys and training participant monthly reflections on inclusion skill development and awareness as it related to their student services role were also reviewed to better understand participant's awareness and described application of their learning. A limitation of this study design is not including students as research participants to include their perspective of inclusion (or exclusion) in a College service interaction space. Outside of the applied research project, student input to an overall perception of inclusion (or exclusion) at NorQuest was collected through art-based inputs in an event called Inclusion Fusion. This event included student created art focused on an inclusion theme, a photography display based on a Photovoice curricular project and a Speakers Corner. Although some students through these activities identified student service staff as important to their feeling of inclusion (e.g. photographing a staff member at a service counter and identifying their smiling face as making them feel welcome); many identified instructors, other students and friends, family, or cultural symbols such as the flag from their country of origin and/or the Canadian flag as important to their sense of belonging. With an action research stance, our first concern was to learn and to enhance the existing service model. Future data collection related to student experiences and service performance is warranted.

Analysis and Results

An integrative analysis approach was used to first juxtapose the data sets and then to analyze the data through a DMIS lens (i.e. quantitative IDI profile for ethnocentric and enthnorelative worldviews and qualitative data describing DMS stage-related perspectives and behaviors) and through a quadrivia lens looking at data from focus group and observation using each quadrant as a theme for analysis (i.e. LR: environments for service interactions and communications; LL: the culture of student services delivery; UR: described and observed service behaviors and UL: described values, beliefs and attitudes of the student services team). Summaries drawn from the analyses were checked iteratively with project team members ensuring linkages with the data and with the leadership team of the participating Student Services departments. The results of this analysis provided the project team with a map of described and observed student services. A brief summary is included here.

IDI Profile Results

In comparing the pre- and post-IDI scores there is evidence of small shift from ethnocentrism towards ethnorelativism within the research cohort. We see this in a slight reduction of the percentage of participants scoring in the ethnocentric part of the continuum.

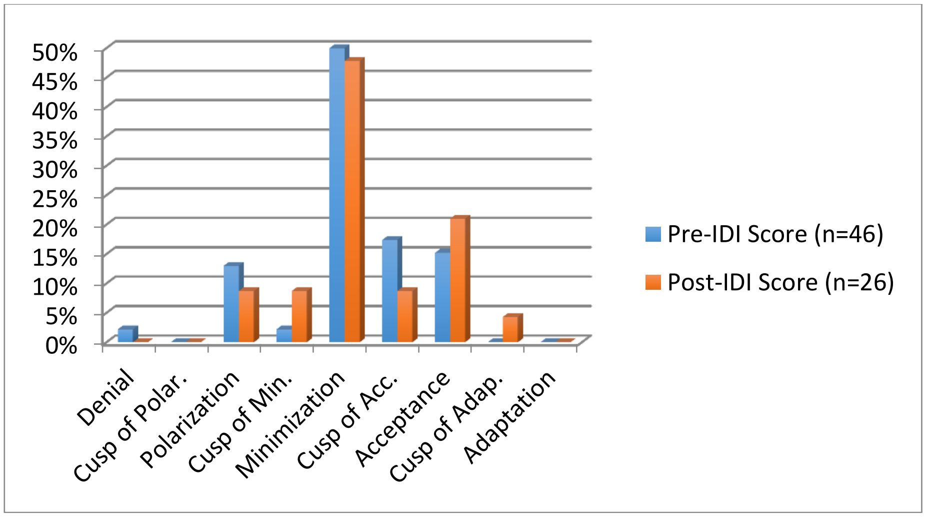

Figure 3. Pre- and Post-IDI Profiles

That shift is reflected in a higher cusp of minimization score (2% Cusp of Minimization in pre-IDI scores to 9% Cusp of Minimization in post-IDI scores). We see a small reduction in Minimization scores (50% Pre-IDI to 48% Post-IDI) and a slight increase in the ethnorelative stages of Acceptance (17% Cusp of Acceptance ;15% Acceptance in Pre-IDI scores to 9% Cusp of Acceptance; 21% Acceptance; in Post-IDI). We also see the emergence of adaptation in post-IDI scores that was not reflected in pre-IDI scores; 4% of participants scored at Cusp of Adaptation.

Limitations that should be noted are the reduced number of participants completing post-IDI scores (46 responders for Pre-IDI compared to 26 responders for Post-IDI). Aggregate profiles for Pre- and Post-IDIs were drawn from all completers at each data collection point as an automated report from the Intercultural Development Institute service. Individual completers were not tracked from pre- to post-scores. It is possible that results are inflated through self-selection bias; participants who chose not to complete the post-IDI may be more likely scoring from an ethnocentric worldview. This may explain the removal of IDI scores in the ethnocentric (Denial, Polarization) stages. It does not, however, account for higher scores in the Acceptance and Cusp of Adaptation stages. Individual score tracking would enable greater precision on what developmental trends occurred for participants in each DMIS stage. This approach would allow researchers to examine questions of how IDI-guided inclusion training affects intercultural competence development by stage and by other demographic considerations, e.g. number of years spent living in another country, racial/ethno-cultural identity etc. At the time of the study, significant change in student services staffing occurred (e.g. position layoffs, re-organization) that would have made individual tracking difficult across the applied research project. Even with these limitations, the overall trend for participants completing pre- and post-training IDIs indicates a small shift towards ethnorelativist worldviews on the intercultural continuum.

Comparing IDI Profile Scores to College Profile Scores

When compared to an aggregate profile of IDI scores collected over the last 2 years, the IDI profile of the student services cohort is representative of a larger staff sample drawn from departments and faculties across the College. A compilation of these results of IDI profiles gathered to date shows that a large majority of College staff members are clustered within the ethnocentric stage of minimization. Our study data is generally representative of the staff overall in the College.

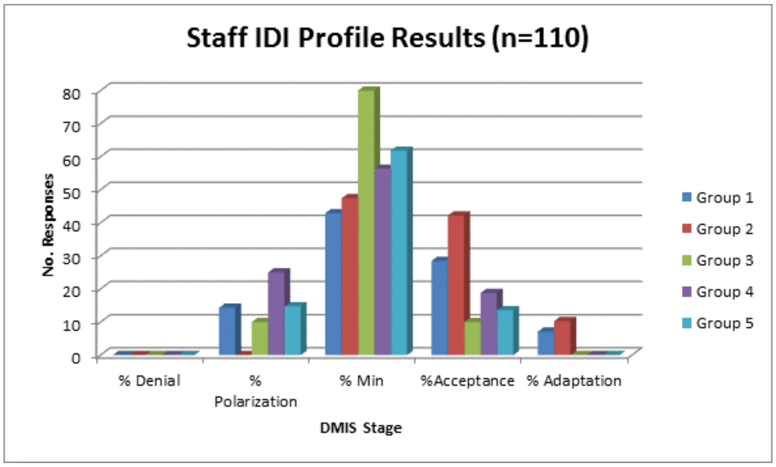

Figure 4. College Benchmark IDI Profile Scores

From a minimization worldview, people from other cultures are pretty much like you, under the surface. Within a minimization perspective, you are quite aware that other cultures exist all around you, and you may know something about cultural differences in customs, celebrations, or other objective artifacts of cultural traditions. You tend not to denigrate other cultures and you seek to avoid stereotypes by treating every person as an individual or by treating other people, as you would like to be treated. One of the strengths of this perspective is recognizing the essential humanity of every person and trying to behave in tolerant ways towards others. One of the challenges of this perspective is the focus on commonalities that can mask deeper recognition of cultural differences. You may miss or minimize the differences that make a difference. So in pursuing a model of inclusion, acknowledging the potential to entrench a mainstream Canadian organizational and cultural view under the guise of helping our diverse students to ‘fit in,’ we decided in the inclusion training to emphasize the importance of creating opportunities for engagement with diverse perspectives. From this minimization worldview, opportunities for growth come through practice in understanding one’s own perspective *and* the perspectives of others.

Results: How is Student Services Perceived?

The following section summarizes the perspectives of student service interactions by quadrant.

Environment for Service Interactions

Interactions happened either within a cubicle/office environment, across a service counter or in a waiting room. Distance between staff and students averaged between two to three feet. Cubicle environments were quiet, favouring one-on-one interactions although exceptions were made for students attending appointments with children or other family members. Waiting rooms and service counters were often crowded and noisy. Staff sometimes approached students waiting with information updates and anticipated wait times. Service counter line-ups observed showed less than a 5-minute wait. Reported wait times were longer during peak times (e.g. prior to semester starts).

Service Culture

Service culture was characterized by providing service, particularly problem solving on behalf of students. Time sensitivity was shared with an emphasis on keeping the wait line moving. Staff demonstrated respect for students, particularly for their past experiences and achievements, and emphasized being treated respectfully by students. Staff emphasized working as teams and the importance of receiving appreciation from colleagues and supervisors. Staff demonstrated conscious knowledge of working within an explicit code of behaviour and ethics in their service to students. Shared challenges included providing a high volume of detailed information to students with communication challenges (e.g. English not their first language, learning disabilities, low confidence to navigate College entrance requirements) and supporting students to navigate a complicated and sometimes confusing admission process, particularly funding and program requirements. Staff expressed interest in learning more about diverse student population (e.g. cultural norms) and demonstrated varying levels of existing knowledge in understanding and communicating effectively with diverse students.

Service Behaviors

Based on observations and focus group data, student service interactions tend to be 15 minutes or less, conducted in one-on-one conversations, typically using information tools including forms, the College calendar or other printed resources and computer-based systems related to student registration, programming, history of services and/or funding. Communication behaviors observed and described include establishing personal connections, conveying respect through verbal and non-verbal behaviors (e.g. attentive listening, asking for permission to leave to retrieve documents from printer), adjusting the pace of speaking (for non-native English speakers), allowing time for students to respond and checking for understanding. Staff demonstrated explaining procedures often using information sources to support clear communication (e.g. highlighting key information as they talk about it). Voice qualities observed included warm tones, energized and clear speaking, calmly repeating information in different ways. Staff demonstrated open body posture, use of supportive gestures (e.g. counts on fingers to review tasks for students), active listening postures, leaning in and facing students while communicating. Less frequently staff were observed communicating with attention on their computer screen. More often staff would maintain attention on the student, talk about what they needed to do on the computer and would then turn to interact with the computer system.

Service Values

Staff described values and beliefs related to service as part of focus group discussions. Staff spoke of their desire to treat all students fairly, with respect and to treat other staff team members respectfully. Staff described their strategies to manage "hot buttons" when challenged by students or difficult service situations. Maintaining credibility was identified often, especially when communicating with students from different worldviews (often but not always related to gender and status). Staff spoke openly about their empathy and appreciation for the challenges and life experiences students face (e.g. students coming from lives in refugee camps; students overcoming economic or social barriers). Knowing that good customer service was provided and acknowledged by students was also important for staff. Challenges in navigating complicated information and funding systems were acknowledged; finding the best way to support students to navigate these systems were identified as important. Staff spoke of their desire to work with motivated students.

We found that many service practices documented in the initial data collection seemed aligned to support inclusive service outcomes, e.g. respectful communication, active listening, checking for comprehension, expression of empathy and relationship tending, and completion of service goals (based on a departmental service standards framework used by Student Services leaders to monitor service performance). Areas for enhancement of communication and increased intercultural communication skills (e.g. perspective taking as in understanding one's own and another's perspective, increased awareness and fluency with different communication styles, increased awareness of cultural patterns influencing behaviors in communication interactions, e.g. perceived gender roles, how credibility is established) were also identified. Given the ongoing challenge of the service role to support students to navigate multiple information and service systems related to admissions, program requirements and funding, we identified the importance of service staff to bridge students into the systems and culture of the College and even into Canadian culture. Staff with bi-lingual competency or personal experience with immigration brought additional skills to connect with students; staff described that students would seek them out specifically in order to be able to converse in their native language or for friendly support rather than to address a specific problem.

Results: Inclusion Training Influencing Service Practice

Data collected from four reflective assessment assignments collected monthly and post-training evaluations was qualitative in nature. Thematically, participants identified increased awareness and skills related to communication, understanding and adapting to engage people with different perspectives. Some participants identified no learning gains, describing their existing service practice as already containing the skills included in the training. Some participants wanted training on specific cultural knowledge to be included in inclusion training. A few quotes to illustrate qualitative feedback to the questions, "What have I learned that is useful in my work?" and "What has changed in how I engage with diverse students?" are included here.

Participants described increased awareness of their own communication styles and enhanced ability to choose a communication appropriate for an interaction.

- *So far I've been reminded to pay attention to styles and strategies I use in communication and be open to trying something new.*
- *To be more aware of my style of communication and the reactions of students and the positive potential of using a variety of styles.*
- *I am more aware of how people are communicating with me and how I need to alter my communication style to make the conversation go where it needs to.*

- *Communication styles and aspects of communication that will help in adapting my approach to a conversation.*

Participant comments reflect different developmental stage relationship with their learning experience. The three comments reflect stances of acknowledging inclusion strategies without necessarily accepting those strategies (i.e. So far I've been reminded…); increased awareness and the potential to use strategies (i.e. cognitive awareness); knowledge about communication to support behavioral change (adapting approach to conversation). Participant responses have been selected to present a range of ethnocentric and ethnorelative worldviews to illustrate the range of learning outcomes for training participants. The responses have been arranged to reflect, as much as is possible, responses across the intercultural continuum from ethnocentric to ethnorelative perspectives.

Participants identified more reflection on service interactions, viewing the experience as an opportunity for learning.

- *Not to take things personally, but to try and understand the reasons behind it.*
- *Think more about the students' POV especially when they do things differently from expected.*
- *I think about the way in which I will have to engage with another individual so that I can successfully meet my goal or better facilitate the meeting of the team goal.*
- *Always learn something new – to be open to gaining perspective into a student's world.*

Participants described in their own words aspects of intercultural competence in service interactions including active curiosity and active listening, understanding how one's perspective can influence interactions with others, being open to other perspectives and suspending judgements of others.

- *I'm that much more aware of the need to slow down, take a step back and recognize the student's perspective as being different from my own. And perfectly acceptable. Don't need to change it or impose my own.*
- *Trying to shake some of my prejudices.*
- *What is driving my conversation? (goals, values, etc.)*
- *I think I am a more open listener and responder.*
- *How my perspectives of diversity impact my approach to people and framework for interpreting situations.*
- *Be open to ideas, people perceptions or my own may not always be the same but appreciate other's observations. Don't take it for granted.*
- *I think it has reinforced for me to step back and try and understand the different factors driving communication…Goals and values might be different, context might add stress – I will recognize this.*
- *To seek out the perception of the other person. Don't assume that he or she is understanding things in the same way you are.*

Participants named their feelings of engaging people in ways that were more or less comfortable.

- *I am more likely to engage with others from other cultures – less timid.*
- *To allow myself to calm down when I am frustrated and wait for students (give them time).*
- *I try to self reflect, especially when the interaction generates any kind of uncomfortable feelings.*
- *More open and willing to step outside of my comfort zone to engage with them.*
- *I try to be open and welcoming. However this activity showed me that I will have to make a conscious effort to always remain open, even though I feel stressed with my job or overwhelmed.*

Participants identified seeking clues to understand the perspective of students in a service interaction.

- *To pay more attention to body language.*
- *I listen for differences.*
- *I try to change my or check my behaviours against student actions/behaviors.*
- *To always check for understanding – to actively engage.*
- *I always take a reading in terms of my effective response and try to think ahead to create openings for communication according to my assessment of what they can hear. Now I have been paying more attention to what style choices I am making and why.*

A few participants identified gaining a new perspective on inclusion and exclusion in service interactions.

- *I learned that some aspects of NQ are unwelcoming for students. I see things with new eyes.*
- *To be a little less self conscious about offending and more open to developing a relationship.*
- *Feel everyone welcome. No matter who they are, what colour they are, what accent they have, they have to feel welcome.*
- *Engage with others to better understand their perspective.*
- *To engage people. To move beyond accepting.*

Some participants identified affirmation of current practice.

- *Nothing. I am capable in communicating well with diverse students by showing respect, encouragement and giving clear info as needed.*
- *My role already requires me to possess good communication skill and adaptability to different styles so it hasn't changed.*

Participants identified a desire to learn more about specific cultures, communication patterns within specific cultures and their expectation that inclusion training should focus more on specific cultural knowledge and less on communication skills and being adaptable.

- *Not much, the information is more about communication than cultural awareness.*

- *I wish I could learn more about different cultures and how they perceive things. I wish there was a chat circle or something so I could hear and better understand their POV.*
- *I would have liked to focus more on how people from other cultures communicate instead of my own communication styles.*

Application of Results

Results were used firstly to design inclusion training (a 15 hour training program delivered as 3-hour sessions over 5 months) to support intercultural competence development within a service context. Results were also shared with leaders in Student Services. This training program was designed to increase interculturally effective and appropriate service behaviour and communication skills and provide a space where participants could develop critical attitudes, knowledge and skills necessary to enable them to interact in welcoming and inclusive ways with diverse students. Training activities included discussion of the strengths and limitations of intercultural competence development stages (as described by the DMIS), critical engagement with service narratives and student narratives of inclusion and exclusion, individual reflections on what service providers bring to the service interaction, practice of communication and perspective taking skills, transfer tasks to bring forward skills practiced in the training sessions to the service context and tips to remind participants of key ideas and skills practiced in the training sessions.

Conclusions: Intercultural Communication and Service Interactions

Question 1: “In what ways might Student Services enhance intercultural communication skills during face-to-face interactions with students.”

We found a need to focus on the enhancement of intercultural communication skills based on a primarily ethnocentric, minimization worldview for student services staff. Specific skills included a deeper understanding of service staff’s own worldview with a focus on identifying preferred communication styles and practicing less familiar, less comfortable styles. We also found a need to focus on practicing perspective taking to reinforce the nature of diverse perspectives and to increase staff capability to check for inclusion in service interactions.

Question 2: “How do NorQuest students and staff perceive current student service interactions at NorQuest?”

Our study primarily focused on NorQuest staff perceptions of service interactions. We found the service interaction is a time-bounded, information intensive engagement space. Staff describing challenging intersections to bridge students to confusing and complicated systems of support (e.g. financial aid, pre-program assessments and pre-requisites). Staff also described challenges with students who were difficult to orient to College systems and services. Staff spoke to and demonstrated a service orientation to meet student needs, valuing students who are motivated and who have overcome challenges to enter post-secondary education at the College. Based on arts-based inclusion events with students, some students did identify student services staff as part of their sense of being included at the College as well as other factors including friends, symbols of their country of origin, symbols of belonging to Canada.

Question 3: “How can IDI guided (Intercultural Development Inventory) training and coaching interventions be used to create inclusive student engagement interactions at NorQuest College.”

We found staff participating in IDI guided training showed slight quantitative gains in intercultural competence as measured by the IDI. Staff responses to gains from inclusion training reflect their respective ethnocentric or ethnorelative stage awareness, showing gains in awareness and to a certain extent competence in adapting communication styles, awareness of intercultural competence within the context of a service interaction (e.g. being open to perspective, suspending judgement, the importance of engaging with others to understand them more fully) and for some participants a new understanding of inclusion and exclusion in relationship to their work. Some staff identified a desire for more specific information about cultures and culture-specific communication styles and some staff affirmed their existing knowledge and service practices as already included inclusion-oriented practices.

These findings created a basis for a deeper exploration of inclusion and intercultural competence and to enter into the work of creating the Inclusion = Diversity + Engagement model for action.

Inclusion = Diversity + Engagement and AQAL: Bringing Together Parts Towards a Whole

It was not originally our intent to develop a model as part of our organizational change project. The *Inclusion = Diversity + Engagement* model for action evolved in our work to elicit and honor inclusion at NorQuest College at individual, group and organizational levels of analysis and engagement. As the work for the applied research project progressed it became clear that we needed a better guide to contain and clarify this real life experiment within our organization. As professional perspective takers, our perspectives were muddled. To that end, myself, my colleague Kerry Louw and Meg Salter from MegaSpace Consulting convened through a series of working sessions to more formally knit together the concepts integrated in our model for action. Through these sessions, we used the *AQAL* quadrant map to generate an organizational map “Looking At” inclusive organizational components and the quadrivia map to generate perspectives of inclusion “Looking As” a student. Our combined practice knowledge of salient organizational change foci including a felt sense of the change levers or acupuncture points we needed to trigger to enliven inclusion at the College. We generated the Intercultural Competence Stretch Goal document (an integration of DMIS stages and the Intercultural Knowledge and Competence Value Rubric) to refine and focus the developmental edge for intercultural competence included at the backbone of the design of inclusion training. Finally, we created key messages related to the question “Why Inclusion” translated to align with Amber, Orange and Green stages of development (*AQAL*) to aid with the internal communications work needed to advance this initiative with College stakeholders and decision-makers.

Aware of the potential to become mired in the details of the theoretical landscape for intercultural competence, we chose theories we could use. Multiple theoretical frames and assessment strategies are called for to extend the partial view afforded by any one of these theoretical approaches to the phenomenon of intercultural competence. The contribution of the

AQAL as a map to hold in view and apply the complex cluster of components related to the construct of intercultural competence in an organizational context. As a model for action, however, the *AQAL* lens is held with an intent to move to action to enhance the intercultural competence and inclusion outcome of the college. Before describing in more detail how *AQAL* was applied, it is helpful to understand in more detail the context in which the Inclusion = Diversity + Engagement was developed and the components we sought to hold together within an *AQAL* map.

The Model for Action is a synthesis of constructs to provide a backbone structure to our inclusion strategy actions. The behavioral skill building focus of Deardorff's Process Model, the DMIS to guide intervention design including calibration of training to align with the IDI profiles of College staff was one pragmatic choice for a theoretical framing of an inclusion strategy. We also chose a recent typology rubric to anchor specific intercultural competence traits in our model. A recent consensus on key characteristics of intercultural competence was identified by a panel of American and international scholars documented in the Intercultural Knowledge and Competence Value Rubric (Association of American Colleges and Universities, 2006). These characteristics of intercultural competence include cultural awareness, knowledge of cultural worldviews, empathy, verbal and non-verbal communication, curiosity and openness. We chose this rubric as a reasonable representation of core characteristics for intercultural competence to use in our *Inclusion = Diversity + Engagement* model for action.

In IDI-guided interventions to enhance intercultural competence, the IDI profiles allow intercultural facilitators to target the DMIS stage development needs of learners and to facilitate both translative and potentially transformative learning. Key to intercultural competence is the capacity to take perspectives on, other than our own. Developing this capacity includes both translative development, the knowledge, skills and attitudes that comprise intercultural competence and transformative development, an increasingly complex capacity to perceive and act through the lens of this competence to engage with diverse people, contexts and interactional containers. The view of similarities and differences from an ethnorelative worldview is transformationally different from an ethnocentric worldview. An ethnorelative view can be said to transcend and include an ethnocentric one.

Our intention in this work was to create an applied framework; at the time of development this meant a background structure to guide decision-making and actions (i.e. proactive strategies in each quadrant for inclusion) and evaluation, guiding what we would check for to assess progress and outcomes. Our model was not seeking to explain the phenomenon of inclusion; rather it was a model to guide our engagement with the phenomenon in context. The unit of analysis for our applied framework is at the organizational level with acknowledgement for individuals and groups within the organization as actors of inclusion (or exclusion). As an organizational change strategy, and, hopefully an embodied one, we were ultimately seeking evidence of co-arising inclusion phenomenon, signs that individuals and groups in the organization had internalized enough of the mind, heart and skill set of inclusion to contribute to an inclusion strategy; in other words to evolve inclusion at the College. The Center for Intercultural Education continues to steward the model and this initiative; however, several initiatives aligning with the inclusion mission of the College have since emerged (e.g. student navigator service) that act on and embody this mission. To understand the model for action, it is helpful to better understand how the AQAL model was applied to focus inclusion-enhancing interventions within the College.

Conceptual Model Two: *AQAL* Looking At Inclusion

As a mapping tool for Inclusion in the College, we applied the *quadrant* lens of the *AQAL* model. Quadrants are the dimensions (Singular: I/interior and it/exterior; we/collective interior and its/collective exterior) to contemplate a particular reality, in this case, the phenomenon of inclusion (Wilber, 2000; Esbjörn-Hargens 2009). By contemplating the existing and possible ways inclusion could become present and real at the College, each quadrant provided a lens to see both the presence of inclusion (and exclusion), possible developmental trajectories to grow inclusion and an organizer to choose the focus for action in creating a 5 year strategy to nurture inclusion at the College. "Looking At" inclusion in this way provided an elegant map to place initiatives, current and planned, to nurture inclusion overall at the College.

Mapping Inclusion – Looking At Inclusion

Upper Left - Interior/Individual Experiential phenomena **Inclusion at Core of Brand; NorQuest Learning Experience**	**Upper Right - Exterior/Individual Behavioral phenomena** **PhotoVoice - engaging perspectives through photography**
Lower Left - Collective Cultural phenomena **Inclusion Fusion - co-create inclusive culture**	**Lower Right - Collective Social & Systematic Phenomena** **Performance Management Guide** **College Wide Learning outcomes - systems of inclusion**

Figure 5. Quadrant Map: Looking At Inclusion [4]

We agree with Susan Cook-Greuter and Sean Esbjörn-Hargens that this use of the four quadrants is practical and useful as a way to "honor the complexity of reality" such that we could approach the issue of inclusion in a more "skillful and nuanced way" (Cook-Greuter, 2004, p. 77; Esbjörn-Hargens, 2009, p. 7). Cook-Greuter notes, "AQ is powerful because we can choose any topic at any layer of depth in any quadrants and explore it from the other three quadrants to gain a fuller picture and appreciation of its interrelationships (Cook-Greuter, 2004, p. 87). The quadrants map allowed for an overview, over time of points of planned activity and to map emergent activities. The overview, however, lent itself to a kind of stewarding governance role for the Center; in some instances the Center led activities in service of the overall map of inclusion; in others, the Center merely contributed to or documented emerging activities to provide an evolving map of the whole of inclusion initiatives at NorQuest.

---

[4] Adapted from Esbjörn-Hargens, 2009, p. 5.

Co-Created Evolution of Inclusion by Quadrant

During the timeframe of the applied research project and in the year following, several activities emerged. Starting in the upper left quadrant, the internally held value of inclusion was re-affirmed and made visible by positioning inclusion as part of the core brand of the College during a re-branding activity led by the College president and the Marketing department. Inclusion is also expressed in the NorQuest Learning Experience policy document. Statements in these policy documents include phrases such as “We embrace diversity and honour inclusiveness” and “Your learning environment embodies diversity. Your uniqueness enriches our college. You will develop skills in cultural understanding to succeed in the global community.” The NorQuest Learning Experience is written from both a student perspective and a College perspective.

Moving to the upper right quadrant, an activity that started as a curricular project, PhotoVoice, became a popular activity that has been repeated by instructors in the years since the project and was added to inclusion training for staff. Briefly, in PhotoVoice, participants are asked to take pictures of inclusion and exclusion, articulating their perspective of what they see in the photo, in their environment, what they think, feel and how they make sense of their community within the College. Sharing their photos and perspectives creates a perspective seeking, intercultural space. Exhibits of these photos, visible artifacts of student generated perspectives have been included in College events like Inclusion Fusion and a permanent installation is housed in central and satellite campus libraries.

Moving to the lower left quadrant, an inclusion culture has been nurtured annually through Inclusion Fusion. The Inclusion Fusion event includes multiple engagement spaces including conversation cafes, the Art of Inclusion, banners to share statements committing to end racism and support inclusion as well as a PhotoVoice display. The event draws students, staff, faculty and community members to share perspectives and engage in community building.[5]

Moving to the lower right quadrant, two systems tools have been generated to support integration of inclusion in curriculum and in professional development. NorQuest uses a system of College wide learning outcomes to identify target learning outcomes for all students and staff. Inclusive Culture outcomes identify various competencies including statements such as “Develop intercultural competencies, including an appreciation for other ways of learning and knowing.” “Challenge personal culture–based assumptions.” “Appreciate how contributions from many people enrich the educational experience and the wider community.” “Demonstrate respect for self and others.” Outcomes at a program and course level are designed to map onto these over-arching outcomes creating linkages between learning activities and learning outcomes. Ongoing curricular development is guided by this outcomes framework.

---

[5] For more information on the activities emerging out of the *Inclusion = Diversity + Engagement* model, see the Inclusive Student Engagement website at http://www.norquest.ca/norquest-centres/centre-for-intercultural-education/projects/completed-projects/inclusive-student-engagement.aspx.

The Performance Management Guide for Inclusion is structured using existing staff performance tools to suggest ways to embed an inclusion focus into professional development plans and a rubric to rate the level of engagement. Using a five point scale, a one rating relates to a professional learning engagement related to inclusion of a limited duration (e.g. less than 5 hours). Increased learning engagement (e.g. 10-15 hours) is linked to a higher rating (e.g. 3 out of 5). The highest ratings relate to both engaging in a learning activity and applying learning to change something in one's job, department or functional area in the College to enhance inclusion for others.

The quadrant view of inclusion supports ongoing monitoring and nurturing of disparate inclusion focused activities and processes. This view supports a connected organizational view linking them directly to institutional performance metrics in ways that address the frequency and duration of engagement as part of the performance metrics. Emerging inclusion initiatives can be added to the overall map of inclusion. From a Center for Intercultural Education perspective, we commit to steward the model to make inclusion more visible at the College, celebrating initiatives that emerge independently of the Center. In the years since the beginning of the project, we continue to look for indications of emergence within the field of inclusion that is held.

Looking As: Perspective Seeking as a Doorway into Embodied Inclusion

The quadrivia approach was another doorway into inclusion, the perspectives of individuals or groups within the College. In addition to Looking At the dimensions of inclusion, organizationally, using a quadrivia approach, we held a perspective of inclusion from the people engaged with inclusion.

Looking As – An Individual Perspective

Looking As a Student

Upper Left - Interior/Individual Experiential phenomena **What I Value, Dream, Think, Believe, Feel**	**Upper Right - Exterior/Individual Behavioral phenomena** **What I Do, What you can see about me**
Lower Left - Collective Cultural phenomena **Who are my people? What groups do I belong to? How do we relate?**	**Lower Right - Collective Social & Systematic Phenomena** **What processes, systems do I interact with? That impact me? What challenges do I face navigating College systems?**

Figure 6. The four quadrants of an individual – doorways into inclusion for a student [6]

---

[6] Adapted from Esbjörn-Hargens, 2009, p. 5.

Each of these quadrants represents dimensions of an individual's awareness; this version of the quadrant maps the dimensions of awareness that can be "channels" to take in information from an experience (Esbjörn-Hargens, 2009, p. 7). All individual(s)…"have or possess four perspectives through which or with which they view or touch the world, and those are the quadrants (the view through)" (Wilber 2006, p. 34 cited in Divine, 2009 p. 36). Divine describes the use of quadrants or the view through an individual's perspective as a way to "look as" the individual in the context of Integral Coaching™. This is an exercise, as much as is possible, to occupy the perspective of another person. In applying the quadrants to "Look As" a student in the context of a student service interaction, we can start to inquire into a student's perspective of inclusion. As a student or staff member, can I share what I believe and think? Can I connect with others through my values/our values? Are there groups that operate in ways that make sense to me, that feel comfortable to belong to? Will my way of behaving be accepted? Will I get the results I expect when I interact with others? Will I be able to reach my goals as I use and navigate the systems and processes in the College? Can I be successful here and be me?

Embodied Inclusion

When creating inclusion training or other engagement activities with perspective seeking intent, it became clear that the adoption of the 6 characteristics of intercultural competence used in the Stretch Goal framework were crucial qualities for facilitators of this inclusion engagement space. We needed to embody, to the extent that was possible, the attitudes of respect, openness, and curiosity, to know and learn about cultural self-awareness, and cultural worldviews and to skillfully use verbal and nonverbal communication. These characteristics support us as we hold the space for perspective seeking in a way that honours each individual participating from their unique perspective. We hold the container for participants to make the effort to try on other perspectives including the edges of where and when a person is most challenged by another perspective. Practice of these qualities supported us to hold open the doorway, to invite each person to engage perspective-seeking activities, learning and empathizing more fully with their own perspective and the perspective of others.

Summary - Mapping Inclusion as a Living Lens

The *Inclusion = Diversity + Engagement* model for action is an attempt to use an integrally informed frame to elicit and honor inclusion at NorQuest College at individual, group and organizational levels of analysis and engagement. The model brings together the all quadrants focus of the *AQAL* by Ken Wilber and the Developmental Model of Intercultural Sensitivity by Dr. Milton Bennett. In this model for action, inclusion is viewed as a perspectival phenomenon and suggests that a socially-constructed culture of inclusion is, in part, based on perspective seeking behaviors and spaces. Out of the applied research project that was used to generate the *Inclusion = Diversity + Engagement* model, one of the products of this attempt was the creation of the Intercultural Competence Stretch Goals document. This document supported the project team to focus more precisely on the developmental edge for inclusion project participants to intentionally serve an organizational shift towards a more ethno-relative perspective of inclusion. As we continue annual activities, the lens provided by the Inclusion = Diversity + Engagement model allows us to hold open the questions: What is inclusion? What can it look like? How can we continue to learn from perspectives of inclusion and exclusion? How are we doing? Do our systems and environments support or deter inclusion?

The inclusion interventions that have been implemented since the project have focused on creating opportunities for an embodied perspective-seeking to shift the conversation of inclusion at the College. These interventions have included annual inclusion training for NorQuest staff and faculty, a PhotoVoice curricular activity that allows students to explore inclusion and exclusion through photography and perspective seeking activities; permanent exhibits of the photographs and written perspectives of the student photographers is on display at both central and branch library locations. An annual Inclusion Fusion event held in collaboration with the NorQuest Student Association hosts a variety of perspective-seeking activities such as conversation cafes, the art of inclusion and a PhotoVoice exhibit. The embedding of inclusion as a core College brand has made the internally held value of inclusion visible at the front and center of the College's public identity. The creating of college wide learning outcomes related to inclusive culture are a tool to integrate inclusion into all college programming as well as to guide faculty and staff professional development. An inclusion-focused performance management resource to support staff and their supervisors to identify both learning and change activities has been created to embed within the College performance management system. At time of writing, other initiatives are emerging such as a student navigator service to support students in navigating College systems.

The quadrivia and quadrant maps of the AQAL model are held as maps to 'look at' inclusion across the College and to 'look as' each other, to the extent that is possible. These maps allow the Centre for Intercultural Education to steward a living *Inclusion = Diversity + Engagement* model that honors and seeks to understand the emergent inclusion initiatives generated by college community members. It is our ongoing practice to hold both of these maps as a guide to change the conversation of inclusion to be a co-creative one. This author continues to hold open her curiosity and receptivity for what is emerging, checking for signs of both translative and transformational competence gains, through ongoing IDI profile data, and through the quality and frequency of engagement with diversity in the spirit of inclusion within the organization. On a personal note, as a veteran of organizational change initiatives within post-secondary education institutions, the *Inclusion = Diversity + Engagement* model for action has dropped more deeply into the bones of NorQuest College than any of the change initiatives I have participated in or led in the past. Each day, riding the elevators in the College, surrounded by women and men from over 80 countries of origin, from First Nations, Metis and Inuit peoples, seeing visible physical challenges and sensing into less visible learning challenges, I am privileged to have the opportunity to focus on creating inclusive doorways for every learner, every one that comes to the College. Being included in that work is a good day for me.[7]

---

[7] Special thanks to Laura Divine and Joanne Hunt, co-founders of Integral Coaching Canada. My work has been made possible as a graduate of Integral Coaching Canada. My personal embodied sense of the *AQAL* as a living legacy of their inspired coaching school and a member of a global community of graduates is core to my commitment to reduce suffering in the name of inclusion at NorQuest College.

Immunity to Change Revisited: Theoretical Foundations for Awareness Based Practices for Leadership Development

Jonathan Reams[1]

Abstract: This article presents an inquiry into how the understanding of Kegan and Lahey's immunity to change process can be enhanced through examining it in relation to two other theoretical lenses, the work of David Bohm and the Arbinger Institute. This is taken as an exemplar of the conception of *awareness based practices for leadership development* which is introduced as the larger focus of the article. A brief review of literature in relevant fields is presented to situate the present work. A set of methodological considerations is described along with the process for the analysis of textual extracts from the three sources. This is followed by a description of ten themes emerging from this analysis. These themes are examined for interconnections and key insights. The discussion centers around two elements. First is the wisdom of self-transcendence in relation to the immunity to change process. Second is how the emerging view of awareness can contribute to understanding leadership development. Concluding reflections summarize the findings and identify limitations of the inquiry.

Keywords: Awareness, immunity to change, leadership development, virtuality of self.

Introduction

In 2009 Kegan and Lahey's *Immunity to Change: How to Overcome It and Unlock the Potential in Yourself and Your Organization* was released. Having just tried out their four column approach for fostering developmental growth (Kegan & Lahey, 2001), I eagerly read, applied and reviewed it (Reams, 2009). Over the six years since then, three things have kept my energy and attention on building a deeper understanding of this work; public interest, personal practice and theoretical inquiry.

The first of these is the growing popularity and use of the Immunity to Change (ITC) process by coaches and consultants in the field of leadership development. Their 2001 book *How the Way We Talk can Change the Way We Work: Seven Languages for Transformation* laid out the basic workings of the four column process. With time, experience and feedback to improve on this foundation, Kegan and Lahey's 2009 ITC update has garnered even more attention. For example Brubach (2009, January) wrote a popular article highlighting their work in *The Oprah*

SOME RIGHTS RESERVED

Magazine. A google search (November 10, 2015) using the term ‘immunity to change’ registered 39,000,000 hits.

In addition to these indications of popular uptake and mainstreaming, a number of articles have appeared engaging in research related to ITC (Markus, 2013; Pinkavova, 2010; van Diemen van Thor, 2014), including my own inquiry into how the ITC process has been used in coaching (Reams & Reams, 2015). This small sample can be seen as evidence that the idea of developmental growth through the use of ITC is not only gaining more mainstream traction but also beginning to be inquired into as a sub-field of research on its own.

The second of these strands is around personal practice. Since my initial forays into applying ITC in the classroom and with clients in 2009, I have run more than 30 ITC processes for various groups and also mentored others in running it. These opportunities for practice, observation and reflection have helped immensely in giving nuance and breadth to my understanding of what is going on in the ITC process.

The theoretical dimension is linked to my ongoing interests in awareness, consciousness and developmental psychology. My Ph.D. research enabled me to combine these with the field of leadership studies (Reams, 2002). Elements of this ongoing theoretical inquiry have appeared in different publications and presentations over the last seven years.[2] In addition, in 2010 I began a process of gathering material that I felt could illuminate additional facets of this inner immune system that the ITC process works with and on.

There are two purposes for this article. One is to enrich the discourse on and understanding of the conception of *immunity to change*. The second is to lay out some theoretical foundations for understanding what I describe as *awareness based practices for leadership development*. To accomplish this, I have done an analysis of relevant textual extracts from the ITC book as well as drawn on two additional theoretical lenses. These are the work of the Arbinger Institute and the work of David Bohm.

A brief review of the broader context of leadership studies which this work aims to influence is presented next. This includes examining a number of related fields pertinent to this project; developmental theory, how it has been applied to leadership, awareness practices and mindfulness, transformative learning and self-awareness. This is followed by a brief description of the methodology employed. I have included an appendix that describes a broader set of methodological considerations for those interested in reflections on the deeper background implicit in such matters. There is also an appendix providing rich descriptions of the key themes arising from the textual extract analysis. The main text continues with a summary of these findings, followed by a discussion oriented around two themes; the wisdom of self-transcendence and how the definition of awareness coming from the analysis can contribute to ideas about leadership development.

---

[2] This has included; developmental approaches to leadership development (Reams & Fikse, 2010), futures studies (Reams, 2010c), conference presentations on the subtle aspects of the quality of presence (Reams, 2010a, 2010b, 2013; Reams & Caspari, 2013; Reams & Gunnlaugson, 2013), integral leadership (Reams, 2012; Reams & Caspari, 2012) , and cultivating leadership through awareness based practices (Reams, Gunnlaugson, & Reams, 2014).

Context

The field of leadership studies is broad, with almost as many definitions of leadership as there are theorists (Rost, 1991). Kellerman (2012) estimates 1400 definitions of leadership, along with 44 theories about it. Beyond the academic domain, there is a very practical need for developing better leaders and leadership as a competitive advantage. From this "there is little doubt that leadership education and development has become a big business" (Pfeffer, 2011, p. 220) with more than $170 billion being spent on leadership curriculum in US businesses (from the ASTD, in Myatt, 2012). Despite all these resources being spent, building leadership talent was identified as a significant challenge in the 2008 IBM Global Business services report (in Day, Harrison & Halpin, 2009). Yet much of the investment in such development is seen to have a limited impact or return on investment.[3] Mike Myatt, in his December 19, 2012 Forbes leadership blog noted that the number one reason leadership development fails is that it is done as training or indoctrination. His solution is to stop training and begin to develop leaders.

It is in this broader context of a generally poor return on investments that the conception of a *developmental* approach to leadership development arises as one solution to the issue. Kegan and Lahey (2009) are explicit about their ITC process being a tool to foster such development, thus situating the main starting point of this project squarely in this approach.[4] In this section I briefly examine literature on developmental approaches to leadership development and other orientations to awareness based practices including mindfulness, transformative learning and self-awareness in relation to leadership. The boundaries of the present article mean that I only take a brief survey of each area as part of the broader context of this project and invite interested readers to follow up on areas of interest through the specific literature cited.

Developmental Theory

Before delving into these subsections, I believe it is worthwhile to take a brief look at key aspects of the developmental theory component of leadership development. (For those wanting a more thorough description of this, see (Reams, 2014)). The lens of seeing human growth in terms of what is called development began with James Mark Baldwin (1895, 1904, 1906) who talked about 'subject – object development' and genetic epistemology. He was an influence on Jean Piaget (1932, 1954, 1970), who adapted Freud's use of clinical interviews to develop a method of semi-structured interviews to study how epistemological structures evolved. While his focus was on this process of epistemological development, he is often more remembered for his classification of stages of development.

From Piaget's developmental stage model, Lawrence Kohlberg (1969, 1975; 1984) drew on John Rawls' (1971) moral philosophy to generate a stage model of moral development. His work had extensive influence in many domains and a large number of his students continued to apply this work in various domains. Contemporaneously, Jane Loevinger (1976; 1970) built on the work of Harry Stack Sullivan (1968) to build both an assessment instrument and theory of stages of ego development. Susanne Cook-Greuter (1999) extended Loevinger's model and worked with Bill Torbert (2004) on applying the assessment of ego development to managerial and leadership domains.

---

[3] It is worth noting that while this article and much of the literature cited here emphasizes the value of self-awareness in leaders, there are many other factors that contribute to how leaders are actually able to be successful in terms of reaching desired outcomes. In conjunction with this, it can be seen that many leaders who appear to have little self-awareness, or are even abusive, still end up being successful.

[4] My review of Anderson and Adams' (2016) *Mastering Leadership* in this issue is another example of a developmental approach to leadership development.

Robert Kegan (1980, 1982, 1994) built on the foundations that Piaget and Kohlberg, and among others established and articulated a sophisticated model of how the self evolves through a series of 'evolutionary truces' or orders of consciousness. His work integrated three major intellectual strands; the constructive-developmental work highlighted above; the humanistic and existential humanistic work of people like Rogers (1951, 1961), Buber (1958), Maslow (1943) and May (1969); and the neo-psychoanalytical tradition from Anna Freud (1993), Erickson (1982) and Winnicott (1965). Along with this, Lahey, Souvaine, Kegan, Goodman, and Felix (1988) developed the subject object interview guide as a way of assessing these stages of development. The shift from describing and assessing development to facilitating it came with the development of the four column exercise (Kegan & Lahey, 2001) and then the updated immunity to change process (2009) that is the focus of this project.

Also a student of Kohlberg, Kurt Fisher (1980; Fischer & Bidell, 2006; Mascolo & Fischer, 2010) developed dynamic skill theory. This approach focused on developing a better understanding of the dynamic relationship between organism and environment and helped to integrate many cognitive development theories' emphasis on the self with behaviorists' (Skinner, 1938, 1969) understanding of the role of operant conditioning from the environment on development. His model is not explicitly about a self or ego and in contrast to most of the theories described above Fischer never uses the term ego in his work. It is a very interactive model, taking biology, structure of mind, social relationships and environmental influences all into account, to develop a general model of development that can be applied in any domain or context. Assessments related to this orientation have also been developed (Commons, Trudeau, Stein, Richards, & Krause, 1998; Dawson, Commons, & Wilson, 2005; Dawson, Xie, & Wilson, 2003) which focus on assessing the development of performance in relation to specific skills, including cognitive skills.

Developmental Leadership Development

The notion of applying developmental theory from psychology to the field of leadership and management studies did not begin with Kegan and Lahey's (2009) approach to the topic. (Of course their ITC process is designed for a broader range of issues, but is often utilized in relation to leadership development). While there may have been others who began earlier, the work of Bill Torbert (Rooke & Torbert, 2005; Rooke & Torbert, 1998; Torbert, 1991; Torbert & Associates, 2004) stands out as pioneering empirical work on the description of cognitive development in leaders and the impact this has on organizations.

Others such as Bill Joiner & Stephen Josephs (2007), David Day (Day & Dragoni, 2015; Day et al., 2009; Day & Zaccaro, 2004) and Karl Kuhnert (Harris & Kuhnert, 2008; Kuhnert & Lewis, 1987; Lucius & Kuhnert, 1999; Strang & Kuhnert, 2009) have also contributed to understanding the relationship between leadership development and structural orders of consciousness. As well, the field of coaching has seen an increased use of developmental theory (Elliot, 2011; Markus, 2013; Pinkavova, 2010; van Diemen van Thor, 2014) with the use of ITC being prominent in much of this work.

Day & Dragoni's (2015) current review of leadership development research identifies four key indicators necessary for leadership development; leadership self-efficacy, self-awareness, leader identity and leadership knowledge, skills and competencies. A developmental perspective is included in this review as a factor influencing all of these. Work over time in these key areas can lead to outcomes such as having more dynamic skills as well as more adequate levels of complexity of meaning making structures and processes. In an earlier survey of developmental leadership development research, McCauley et al. (2006) identified a need for moving beyond a focus on "developmental order to include the general dynamics of developmental movement" (p. 648). Palus and Drath (1995) addressed this and focused on the process involved in creating developmenally oriented programs.

This brief description of some key research at this intersection highlights that this approach to leadership development is not new. At the same time, it has not been widely adopted in the mainstream of the field of leadership studies.

Awareness Practices and Mindfulness

A very early influence on me around awareness practices was Tim Gallwey's *The Inner Game of Tennis* (1975), which I bought when it came out both because I played tennis in high school and because there was some felt sense of resonance with the title. His concept is of self 1, a conscious ego mind that likes to judge and critique performance and self 2, a non-judgmental awareness that witnesses, absorbs and learns by doing. This model was extended into the workplace as well (Gallwey, 2000), making it one of the most relevant precursors for this current project. Kahneman's *Thinking, Fast and Slow* (2011) talks about systems 1 and 2 in a way that both reinforces Gallwey's conceptions (although it has the opposite associations to the numbering) and provides a much more detailed exploration of understanding of how these systems work.

Eugene Gendlin's work *Focusing* (1981, 1996), describes his research into what actually makes therapeutic processes effective. This includes a six step process for getting in touch with the 'felt-sense' of a subjective phenomenon. My own experience from using this process has helped develop some of the capacities required to undertake this project. The combination of Gallwey and Gendlin's early influences on me is part of the 'groundwork' noted in Appendix I as part of the methodological considerations behind this project.

Searching google scholar for 'awareness based practices for development' turned up primarily unrelated hits, with some work on mindfulness practices showing up. Using Academic Search Complete, with the terms 'awareness based,' 'practices' and 'development' in abstracts, there was still a diverse set of results, with a few studies of mindfulness again being the most relevant. Changing the search terms to 'awareness practices' and 'development' returned similar results.

From this, a brief look at some elements of how mindfulness practices are being utilized in relation to leadership is warranted.

Mindfulness has its roots in Buddhism as the seventh element on the noble eightfold path. The Pali and Sanskrit terms can also be translated as awareness. In recent decades the core principles of mindfulness have been developed in secular contexts, most notably by Jon Kabat-Zinn in the Mindfulness-Based Stress reduction program at the University of Massachusetts Medical School. He defines mindfulness as "paying attention in a particular way: on purpose, in the present moment and non-judgmentally" (Kabat-Zinn, 1994, p. 4). From this, mindfulness-based practices such as presencing (Senge, Jaworski, Scharmer, & Flowers, 2004) and deep presencing (Gunnlaugson & Walker, 2013) provide a path for applying mindfulness in organizational, leadership and coaching contexts. From this it is apparent that awareness practices are being used in relation to leadership, even if they are not widespread.

Transformative Learning

A brief look at the field of transformative learning can also provide some useful context for this project. The seminal work of Jack Mezirow (1990) provides a foundation for this. In looking at the question of what *form* is transforming, Kegan (1980, 1982, 1994) focuses on the cognitive form (rather than the content) of the learner’s structure of meaning making. He organizes this into five orders, of which the third and fourth (socialized mind and self-authoring mind) address the vast majority of the adult population.

The journey through these orders of structuring meaning making, (and by implication how one perceives, interprets and acts in their role as a leader), utilizes critical reflection on deeply held frames of reference, or assumptions. This can be experienced as having rational as well as intuitive or emotional components. Integrating Mezirow’s ten steps for transformative learning and Kegan and Lahey’s ITC process, it is possible to describe major steps along this journey as including; encountering disorienting dilemmas, being able to inquire into their underlying sources, exploring options for testing the validity of assumptions, gathering data on such tests, building new frames of reference and enabling new orientations, attitudes and behaviors. Palus and Drath (1995) describe how experiential development programs for leaders can support this process and generate new possibilities for leadership development.

Self-Awareness

Central to many of the above concepts and a centrally addressed in this project is self-awareness. Socrates was famous for citing the Delphic oracle in saying that the first condition for being human was to “know thyself.” The cultivation of leadership aimed for generating a philosopher king, and the training of young men to prepare them for roles in the ideal Republic (Plato, 1992) was aimed at cultivating self-awareness. Linked to this is what the notion of self was seen to be. Plato’s (1954) description of the last days of Socrates framed this in terms of the doctrine of the immortality of the soul. This theme of self and soul has reverberated through the ages in philosophy and religion and appears today in the study of leadership as well.[5]

Focusing on current research related to self-awareness and leadership, Axelrod (2012) examined self-awareness in relation to psychotherapy and coaching, noting the critical role of emotional awareness. Self-awareness is linked to emotional intelligence competencies of “accurate self-assessment, emotional awareness and self-confidence” (p. 345). Goleman (2006) noted the importance of emotional awareness and social intelligence, citing recent neuroscience research into mirror neurons saying that “whatever the supposed business at hand, we continually transmit emotions, making another feel better or worse” (p. 78). McCraty, Atkinson, Tomasino, and Bradley (2009) describe extensive research in the field of neurocardiology that substantiates this and indicates our ability to sense the electromagnetic field produced by the heart at up to three meters. This ongoing transmission of emotions contributes to what Kegan and colleagues (Kegan, Lahey, Fleming, & Miller, 2014) describe as our ‘second job’ where we spend a great deal of time and effort to wrestle with the daily implications of how this social-emotional environment plays into our personal growth. Thus awareness of our own state at an emotional level, and the ability to take a perspective on others to enhance social intelligence are critical capacities for leaders.

Self-awareness itself, as a construct in leadership research is approached by many theorists. Fusco, Palmer, and O'Riodran (2011) note that “self-awareness … is the first of the four constructs shown to underpin authentic leadership” (p. 130). Ashley and Reiter-Palmon (2012) note that “empirical support is mounting suggesting that self-awareness is related to leadership such that leaders higher in self-awareness tend to get better outcomes than those with lower levels of self-awareness” (p. 2). Axelrod (2012) likewise says that “the critical importance of executive self-awareness for organizational effectiveness has been frequently noted by a wide array of modern leadership development experts” (p. 340). The growing acknowledgement of the central role that self-awareness plays in leadership and its development makes research into the actual workings of an awareness based approach of critical importance.

This brief survey of background literature provides a contextual backdrop for some of the areas relevant to this project. The next step is to go into an in depth examination of the three focal sources chosen for this project.

Background and Contextualization of the Three Sources

Before delving into the details of the methodology and data analysis, it is worth taking a moment to present some brief background on the context within which each of these three sources arose. The three sources are; Kegan and Lahey’s (2009) *Immunity to Change*, David Bohm’s (1992) *Thought as a System*, and work from the Arbinger Institute (1997, 2006, 2010; Warner, 2001).

---

[5] There is plenty of popular and even well researched literature along this theme (Bolman & Deal, 1995; Chopra, 2010; Conger, 1994; Doetzel, 2006; Dorr, 2006; Hawley, 1993; Nelson, 2002).

Kegan and Lahey's work is the focal point for this project, taking a primarily psychological and developmental lens. Robert Kegan's early (1982) work was described above. Later, along with Lisa Lahey, the four column exercise (Kegan and Lahey, 2001) was developed as a practical tool to support development and was later refined into the immunity to change (2009) form that is in widespread popular use today. Minds at Work is the current business vehicle for spreading their work into the world.[6]

David Bohm's lens arises from a very different background. As a physicist, his PhD was signed off by Oppenheimer as part of the Manhattan Project. He developed the field of plasma physics after that, then wrote serious critiques of the Copenhagen interpretation of quantum mechanics. His association with Marxism while at Berkeley led to fleeing the US during the McCarthy era, eventually settling in the UK. His approach to understanding quantum physics emphasized wholeness (Bohm, 1980; Bohm & Hiley, 1993) and utilized a holographic metaphor. He was also influenced by the mysticism of Jiddhu Krishnamurti (1994) and this contributed to his influential work in the field of dialogue (e.g. Senge, 1990; Isaacs, 1999). His lens as used here appears as an attempt to support processes for gaining coherence in the system of thought (since the text is a transcript of a pre-dialogue group seminar), by understanding the nature of thought itself and its limitations.

The Arbinger[7] work derives from Terry Warner's (1997; 2001) work to understand the fundamental ethical character of being human and from this the phenomenon of self-deception. His background is as a professor of philosophy at Brigham Young University. He also spent time at Linacre College at Oxford where some of his seminal ideas developed. The Arbinger Institute was founded in 1979, and its work expanded significantly upon the publication of *Leadership and Self Deception* in 2000 (which has sold over one million copies and is available in 27 languages). Today they have offices in 20 countries and support individuals and organizations in improving culture and resolving conflict.

This represents three lenses that I have utilized in this project which can be characterized as; psychological, objective and ethical, all being applied to a phenomenon at the heart of the human experience, the gap between our aspirations for change and our ability to achieve the changes we wish.

Methodology

In this section I describe the methodology used in this project. There are two main aspects of the methodology. The first is a set of considerations relevant to the approach to and preparations for the project. This is described in more detail in Appendix I. Briefly, this set of considerations begins with the notion of *bricolage*, or a bricoleur as someone who "works between and within competing and overlapping perspectives and paradigms" (Gidley, 2007, p. 6). From this orientation comes the sense that my goal in this project is less to show *findings* in an empirical sense and more to reveal a sense of *feeling into a view*.

---

[6] Through Minds at Work they also train coaches to work with this process and I have been fortunate to work with a number of individuals who have been through this training.

[7] In this article, for convenience I use the term Arbinger to cover both the writings published under the corporate name of The Arbinger Institute (where they explain that multiple authors involved chose anonymity to focus on the work itself) and the work of founder Terry Warner.

There is a clear sense in which this project falls under the heading of metatheory. Edwards (2010) includes a number of steps in undertaking such work: groundwork, domain specification, design, multiparadigm review, multiparadigm analysis, metatheory building, implications, and evaluation. How these are addressed is outlined in Appendix I. The nature of this project also has a strong heuristic element. Here I worked with a sense of using my own sensitivity to the subject of inquiry as a kind of ‘tuning fork’ to look for resonances. Finally, interpreting the data required a hermeneutic orientation as well. All of this served to dynamically steer the research process.

I employed this set of methodological considerations as I undertook selecting quotes from the texts that form the basis for this project. For the content analysis of these textual extracts I was able to draw on a more analytical set of tools, specifically in the form of using the NVivo 10 software program to perform various analytical manipulations.

The first step in this process was the reading of the above described texts with an eye towards statements that were perceived to have some relevance to the overarching theme under consideration. This yielded 19 pages or 9146 words of statements (with some brief reflections related to them in the set of Arbinger notes), which were loaded into NVivo 10 in three files, one for each source.

Queries, or analyses performed by NVivo on the texts, were done at five levels of word specification: exact, stemmed, synonyms, specializations and generalizations. Specifications for these queries were given for a four letter word minimum and up to 100 results (see Appendix II for tables of the most relevant results for each query). This resulted in identifying ten terms as most relevant for further investigation: change, cognitive, conscious, feelings, immune, make, others, self, system and thought.

Using a coding function in NVivo, nodes, or categories of data, were generated by the program for each of the results from each query (the ten themes listed above, with a node for each time each of those ten themes occurred in one of the five levels of specification listed above). These nodes contained each term found by the query with five words prior to and after the term as they occurred in the text.

This set of ten terms was then used to create new nodes. These nodes were populated by manually going through the coded text from each of the original query node results (which ranged from 32 up to 495 items) and copying relevant text that illustrated the various uses of each term until each new node was populated with a saturated set of phrases around each of the ten terms.

Each of these ten nodes was further analyzed to produce a table that listed descriptions of how each of the three views used each of the ten terms. (This table, with summaries included, came to eight pages with 1700 words and is not included here). These 30 sets of the uses of the ten terms were then summarized to draw out a more essential description of themes emerging from the selected text excerpts. This resulted in a two page table, with the key constructs related to each set of three uses of the ten terms (see Appendix III). These results form the basis of the key themes in the findings section.

The next step was to examine the conceptualizations and uses of each of these ten terms in relation to the original body of textual extracts used for the data analysis. NVivo provided highlighted text within the full text related to each of the items in the ten nodes, making it easy to see them in their broader context. Examples from this step were used to illustrate the key themes. A rich description of these ten themes is found in Appendix IV. Finally, once this summary and illustration of the ten themes was complete, they were reviewed in order to examine how the themes intersected, overlapped and informed each other.

Findings

In this section I describe the results of this textual content analysis into the conceptual relationships between the three sources of data used for this project. This consists of two parts. The first is found in Appendix IV, providing an extensive description of the ten themes that emerged from the textual analysis. They are presented in the order of; self, conscious, immune, system, others, feelings, change, make, thought and cognitive.[8] In the second part starting just below, I weave these key concepts into a more integrative sense of what the juxtaposition and combination of these three views can produce.

Following from the description of the ten themes described in Appendix IV, the next step in the process of making sense of this set of data was to review those descriptions and illustrations by using the two focal points set out at the beginning of this article. The first was to look for conceptions that could enrich the understanding of the immunity to change process. The second was around building a foundational conception of what awareness based practices for leadership development could look like.[9]

It is clear that there are also many other possible connections, interpretations and implications that could be focused on. Here, it is clear that I have relied on my tacit knowledge to look for interpretations that aid in making this notion of *feeling into a view* more explicit, which was noted in the methodological considerations as being one of the purposes of this project.

Weaving Threads

One simple observation was to notice that linking the first four terms analyzed (according to the criteria I used for ordering them), one gets the conception of a *self-conscious immune system*, which presents an interesting phrase loaded with possible implications. Also, arising from the analysis of the first two terms was an observation that there is a clear distinction between being self-conscious (or having attention focused on a self that is produced by the system of thought) and being aware, or awareness in itself. This is linked to the distinction made in relation to the term self, where Kegan and Lahey appear to use the term self as a given, an identity or ‘entity,’ while both Bohm and Arbinger utilize the concept of self in more in connection with illusion, incoherence or deception. The notion of the *virtuality of self* (Rowson 2008) is relevant here, and will be brought forward in the discussion below.

---

[8] This appendix can provide a number of pieces of background information that readers may find useful. In addition to summary descriptions and quotes to show in some detail how each of these terms were used, there are also comments that might clarify questions arising, such as why certain terms are in this list, the order of the presentation of the terms as well as how they are used by each source.

[9] While the influence of first focal point is relatively easy to spot in the following, the second one is not as obvious. However, I believe that the influence of attending to it becomes more visible later in the discussion.

Further disentangling this set of threads, Kegan and Lahey talk about the immune system as something that operates automatically, as something we are unaware of. Bohm talks about it this way as well, but extends this into describing the resistance in the system of thought specifically to the avoidance of unpleasantness. Arbinger talks about an anxiety management system similar to how the immune system is described by Kegan and Lahey. They link this to constant resistance and the assertion of self.

Looking deeper into what is implicit in the conception of being self-conscious, how the term change is used becomes relevant. Change is linked to the self-image dying. The conception of a self and being conscious of it, (being ‘self-conscious’), is linked to how the system of thought is invested in maintaining all this by keeping our attention directed *to* and *through* the self. At the same time there is a link between the self-image dying and awareness as distinct from this self-consciousness. This will become an important distinction later.

Kegan and Lahey’s (2009) core concept is all about this immune system. As the second pair of terms in this initial configuration, the notion of an immune system is seen by them as “making a mistake sometimes” (p. 37). This can be connected to a lack of awareness and later to incoherence. While Kegan and Lahey’s description of our psychological immune system is drawn from its biological equivalent, Bohm’s description is of a set of reflexes that include thought, feelings and physiological aspects like electrochemical impulses in the brain as well as including the whole of society.[10] How this system of thought impacts other relevant aspects of this inquiry will be taken up later.

Moving on to examine how the conception of others is used, the distinction between awareness and self-consciousness comes up again and can be linked to Arbinger’s notion of collusion. In this concept, the lack of awareness is tied to being self-conscious, which leads to inviting others to participate in collective self-deception. There is a link, (possibly implicit in this view), connecting the notions of self-consciousness and self-deception. One way to derive that implication is from seeing how Arbinger describes our way of being towards others as touching our deepest sense of right or wrong. The shift we are looking for, (explored more below), comes from attending to “the light coming from others” (Warner, 2001, p. 51).

Feelings come into the picture as well, and Kegan and Lahey are clear that it is necessary to engage them for the ITC process to work. At the same time Bohm describes the feeling of necessity as contributing enormously to resistance (or immunity) to change. This feeling of necessity, or ‘it cannot be otherwise,’ or even ‘don’t yield,’ is a core way in which feelings impact our immunity to change. If our big assumption implicitly says ‘don’t yield’ and is linked to an automatic set of reflexes acting outside of awareness, then how do we imagine affecting it? While part of the answer provided comes later, here Arbinger describes the distinction between feelings of deception and our moral sense being corrupted, from the liberation possible from a correct understanding (or coherence in Bohm’s terms) of a given situation.

---

[10] I notice a similarity here with the conception of memes as carries of ideas and culture across society. There are also similarities to how the notion of ^{v}memes is used in the work of Graves (1974) and Beck and Cowan (1996).

Moving deeper into seeing how the possibility of (or resistance to) change is perceived, Kegan and Lahey talk about change in terms of moving aspects of our meaning making from subject to object. According to Bohm, resistance to this comes from unpleasantness, identification and the reflexes around necessity. This necessity is also tied to the self-conscious identity produced by the system of thought, all happening outside of awareness. Arbinger adds nuances to this in that unpleasant emotions seen as are inherently dishonest and thus “intrinsically resistant” (1997, p. 9) to change. Both Bohm and Arbinger note that this is not a passive process, but that there is an active participation in creating deceptive perceptions from inserting representations of thought into perception or the projection of accusations. All of this points to change needing to come from somewhere deeper than thought, or self-consciousness.

This kind of active process of creating reality is how Kegan and Lahey (2009) talk about the function of the immune system. However, this reality can be guided by “false belief” (p. 50). For Bohm, the most fundamental of those false beliefs is the one where the system of reflexes of thought creates images of reality then inserts them into perception while denying its active role in doing this. Extending and linking this to the domain of the self-image, Bohm (1992) also describes how the system of thought gives false information and “produces the thought that it is *I* who am doing everything” (p. 92) and that we have this feeling that we are the ones controlling thought. In this sense, the notion of self is a virtual construction of the system of thought.[11] Arbinger (1997) adds to this by describing how “we live a lie” (p. 8) that then takes the shape of an accusation, which directs attention away from this process and externalizes any problems by blaming others (also described as justifying ourselves).

While Kegan and Lahey’s description of change in the immune system is framed in terms of subject object shifts, Arbinger describes this change in terms of making distinctions between the light and darkness as a way to know the difference between right and wrong. They show how our conscience can be deceived, since it is a faculty connected to cognitive functioning. From this it can be surmised that the place from which subject object shifts are made is not thought, but a place from which we can direct attention.

For Bohm (1992), the result of directing attention is described in terms of coherence or incoherence. It is also pointed out that insight is something that has the possibility to be outside of the entire system of thought. This offers an opening to a place from which we can direct attention towards generating coherence in thought. Insight can improve coherence through its re-hardwiring of the system of thought. The process of accessing or coming from insight results not only in greater degrees of coherence, but also of freedom understood as “the creative perception of a new order of necessity” (p. 220). This can be viewed as another way of talking about Kegan and Lahey’s notion of transforming our immune systems into a bigger better one, or even changing the big assumptions that govern the immune system. So even if this reality that the immune system produces is virtual, governed by what is taken as necessity, we can improve the nature of this virtual reality.

---

[11] This theme of the virtuality of self is taken up at length in the discussion.

Using the language Arbinger provides, we can describe this in terms of moving into the light or truth that life instructs us with. The lack of light is of course darkness, where we lose our capacity for discernment or the choice of where to direct our attention. If we wish to direct our attention in such a way as to gain freedom from the constraints and limitations of our immune systems, then we need the light of insight.

Summary

Kegan and Lahey (2009) are clear that we cannot think our way out of this immune system, which naturally tries to "save our lives" (p. 50). Following from the inquiry above a question arises: is this immune system actually trying to save the life of a virtual self-image that the system itself creates? They describe how it is necessary to use both a change of mindset through subject object shifts and behavioral change through action in order to effect lasting change that is transformative. This can result in fundamental changes to the structures of the meaning making that we are subject to. However, this investigation has aimed to explore ways to deepen and broaden our understanding of how to overcome this immunity to change. What can we say in addition to their prescription for change?

From Bohm we can see that the resistance of the immune system is from the system itself, even to the electrochemical reflexes in the brain that precede conscious intention. Thus for change (at least change in the direction of coherence) to happen, it is imperative to be able to access a space or source outside this system and this is described as insight. At the same time there is a distinction between self-consciousness, or a self-image, and awareness. Bohm describes this kind of awareness as being proprioceptive in relation to the system of thought, or able to be aware of the functioning of thought as it is happening, and thus in a position to have insight or discernment in relation to the coherence or incoherence of the thought arising.

From Arbinger it can be seen that all these cognitive processes are linked either to self-betrayal (and the chain from there into self-deception and justification), or to perceiving the light of truth. The former is synonymous with propping up an idealized image of ourselves which is intrinsically embedded in darkness and the inability to use our conscience or moral sense to get ourselves out of the situations we are in. In the light of truth lies our hope.

Kegan and Lahey want to transform the immune system and say that it even tries to "save your life." Bohm sees this system as functioning in an incoherent manner, (at least left on its own); while Arbinger says it needs to die. Can Kegan and Lahey's method be seen as trying to make the system of thought more coherent? Yet does this process itself become a dead end or at least give limited returns at some point? Is the next step to perceive the immune system and self it produces as a virtual entity, somehow of value and useful for our experience, but also in the end hiding something essential and critical? Does this self need to die in order for "sensitive human beings" (Warner, 2001, p. 77) to emerge?

The notion of necessity in relation to self appears to be a key link holding the fundamental resistance to change in place. This is also tied to how we conceive of identity. Bohm notes that an alternative orientation or conception could be the idea of moving to a creative rather than identified sense of being. This creative sense of being is also linked to proprioceptive insight, or awareness as something outside of the system of thought. This is also linked to "the light, or source of our understanding of right and wrong" (Warner, 2001, p. 133) as a source or space outside the darkness of the system of thought when it is incoherent.

This summary has aimed to draw out the most essential points coming from the analysis of textual extracts from the three sources. It also represents the result of using the heuristic approach of trying to make tacit knowledge explicit through working with what stands out or resonates in these extracts and the results of analyzing them in relation to each other. From this phase of the project, it is now time to turn attention back to the starting points of this inquiry and discuss these findings in relation to a larger discourse.

Discussion

How can the lenses from Arbinger and Bohm add depth or even offer new possibilities to Kegan and Lahey's descriptions of the immune system and how to change it? Some answers to these questions have emerged above. However, as noted above, the aim of this project is not to come up with answers, (although if some emerge that is ok), but rather to give a sense of *feeling into a view*. Thus the main goal of this discussion is to explore how this view can shine light on various aspects of the phenomenon under study.

The second major question this article focuses on is about what can we learn about the role of awareness in leadership, change and transformation processes? In relation to these two questions, the discussion that follows is made up of two parts. The first section is around the findings just described and possible interpretations, implications and links for the ITC process itself. The second section is to broaden attention back out to the larger context of leadership development and see how the conception of awareness based practices can influence leadership development. In keeping with intention of bounding the scope of the current project I focus on two key elements for this; self-transcendence (and the implication of wisdom in it) and awareness in relation to leadership development.

The Wisdom of Self-Transcendence

In reflecting on the implications of all of the practice, energy and thought (by not only Kegan and Lahey but also by an ever growing number of practitioners), that has gone into the development and practice of the immunity to change process, I have the feeling that there is a generally held, even if implicitly, view that it is somehow *wise* to be able to overcome our immune systems and no longer be subject to limiting or incoherent big assumptions. Emerging from the inquiry at the heart of this project, the most central big assumption revolves around the identification with a sense of self.

The Virtuality of Self

Bohm’s description of the system of thought as a set of electrochemical reflexes in the brain that precede conscious intention has been seen elsewhere, most notably in the experiments of Benjamin Libet (Libet, 1989, 2003; Libet, Gleason, Wright, & Pearl, 1983) who found that neural activity preceded conscious intention by up to half a second. This research reinforces the view that the self-conscious being that we experience as making choices is somehow functioning outside of (or at least in a limited domain relative to) an awareness of what is actually going on. Thus this perspective that the system of thought or immune system acts ‘outside of awareness’ continues to reinforce this distinction between awareness and self/self-consciousness. Can the conception of self as virtual that was alluded to earlier (Rowson, 2008; Varela, 1999) help us see other ways of relating to self?

To explore this further, it is worth delving into Rowson’s (2008) description of the conception of the virtuality of self.[12] Rowson describes what happens when we step beyond our conventional constructs in a way that is similar to what has appeared in the present inquiry: “I suggest that the structure we are stepping out of is our constructed and often limiting notion of our own self, and the ‘shock’ and ‘break’ we feel is a glimpse of our own virtuality” (p. 86). The roots of this concept have of course been with us for a long time.

> The idea, in essence, is the traditional Buddhist claim that selfhood is a powerful and functional illusion, but is ultimately groundless, and that in becoming aware of the ways in which our sense of self is constructed and maintained we free ourselves from some of the limiting assumptions that hinder the development of wisdom. (p. 4)

If we take it to be generally true that we think it is wise to overcome our immune systems, then this perennial view about the wisdom of transcending a tightly identified sense of ourselves (see also for example Plato (1992) or Walsh (1999)) can play a key role in understanding how to work with the immunity to change process.

To explore this further, it is worth taking another step along the line of reasoning Rowson (2008) presents. One element of this is that we need to get out of the system of thought itself to have direct experience of this place of awareness, light or insight.

> So even when one accepts that the self is some kind of persistent illusion or theoretical construction, you can’t just ‘snap out of it’, … The more challenging question is whether and why we might function more wisely if we became more fully aware of the nature of self, and not just in terms of comprehension, but experientially. (p. 179)

It is this aspect of *experientially* that is crucial here. This experience would seem to be about a more coherent or direct awareness of reality, less (or not at all, but that is a larger discussion beyond the scope of this article) mediated by the inherently limited representations of the system of thought, or alternatively, creating more coherent representations. At the same time, as Rowson indicates, we do not suddenly ‘snap out of it’ and perceive reality in a radically different way.[13] It seems we need some representations to utilize in mediating our experience, and thus the search for more coherent ones.[14]

---

[12] This is in the context of his Pd.D. work (2008): *From Wisdom-Related Knowledge to Wise Acts: Refashioning the Concept of Wisdom to Improve our Chances of Becoming Wiser*.

Awareness and Insight

In searching for examples of such representations, Deikman (1996) equates “I” with awareness. He distinguishes between *I* and self, saying that “this ‘I’ should be differentiated from the various aspects of the physical person and its mental contents which form the ‘self’” (p. 350). For Deikman, who we are *is* awareness, the ‘I’ that observes the contents of experience (yet also having its ground of existence independent of the contents of experience).

From this and Rowson’s line of thinking above, I perceive that to be able to proprioceptively and coherently perceive the virtual nature of self appears to be the epitome of wisdom. “The realization that the self is virtual brings with it the balance of knowing and doubting, the openness to experience and the psychological mindedness that I have already suggested are central to wisdom” (Rowson, 2008, p. 194). This act of realization is “ontologically different from perceptual knowledge” (Deikman, 1996, p. 355). It could be said that it is one way of talking about feeling into a view.

To access this kind of realization of awareness “experientially has a transformative effect” (Rowson, 2008, p. 192). In terms of Kegan and Lahey’s immunity to change process, the transformative effect comes from a combination of the subject object shift and taking action in the world. They say that this transformative effect is not “accomplished by just seeking ‘insights,’ as empowering or clarifying as those insights might feel” (p. 222). They go on to show how “understanding more and more deeply what motivates us” (p. 222) is in itself insufficient for transformation. From this it seems worth investigating how they are using the term insight in relation to what has been found in the inquiry undertaken in this article.

It appears that Kegan and Lahey’s use of the term insight is not the same as Bohm’s. It seems that their use allows for insight to be something that occurs within the immune system. This is in the sense that the ‘self’ has an ‘insight’ which Kegan and Lahey point to as insufficient, requiring action to supplement it in order for the transformative change to occur. Coming from Bohm’s view, this kind of insight, that is had by the self, is not the same as insight coming from beyond the system of thought and thus from beyond the self that system constructs. In this latter case, insight is more related to awareness, or maybe that it comes from awareness and the self merely receives it. However then, as noted by both Bohm and Arbinger, the self lays claim (incoherently, or as an act of self-deception) to the insight as being something that it generates itself.

---

[13] Although there are certainly many reported cases of such experiences, they are not the norm and beyond the scope of this article.

[14] There is also an entire discussion about how any direct experience is at some stage interpreted by this system of thought according to our level of cognitive functioning, as well as cultural and other socially constructed influences. To what degree coherence relates to (or does not relate to) cognitive development stages is another matter, but that is also beyond the scope of this discussion.

How does this distinction between self and awareness impact the use of the term self-awareness as noted in the literature review? There the construct self-awareness appears to be utilized without so much explication of the deeper ontological assumptions implicit in it according to the view laid out in this inquiry. In the way it is used in the literature reviewed above, the notion of self is more like how Kegan and Lahey use it, as an identity or entity. Awareness of self is linked to constructs like self-assessment, awareness of our emotional states, or of social relations. One definition given is that self-awareness "is an inwardly-focused evaluative process in which individuals make self/standard comparisons with the goal of better self-knowledge and improvement" (Ashley and Reiter-Palmon, 2012, p. 2). It is apparent that the deeper distinction generated from the present inquiry is not readily apparent in such uses of the term.

Coherence

From these reflections and explorations it is possible to give a preliminary description[15] of awareness as *the experiential realization of the virtuality of self*. Along with the insight coming from such realization, awareness enables a different possibility for transformation than insight appropriated by a self that is part of the immune system. This also has to do with coherence, in contrast to the very fundamentally incoherent act of the constructed self appropriating insight, (or reducing insight to something reinforcing the system of thought and self-image), and then claiming to be the source of insight.

This raises a question around ethics. How ethical can such a self-deceptive process be? There is a fundamental self-deception that comes from the system of thought keeping us tied to identifying with this virtual self. For Arbinger, the move from the darkness of such self-deception into the light is characterized as an ethical move. We can see this in Varela's (1999) thought when he claims that "ethical know-how is the progressive, firsthand acquaintance with the virtuality of self" (p. 63). This matches up very nicely with Arbinger's view of the implications of an I-Thou relationship (Buber, 1958) being the fundamentally ethical basis from which to engage others. In particular, we are encouraged to focus on the transformative effect that comes from acting on the impulses we realize coming from the light of humanity in others. For Arbinger, the ethical use of cognition is in turning our attention to this light.

Immunity to Change Revisited

To bring this back to the examination of the immunity to change process, it is possible to frame the micro subject object shifts Kegan and Lahey describe in terms of dis-identifications. The move of dis-identifying with various aspects of a notion of an identified self that we have been subject to can then be seen as an ethical move, or even in terms of being more coherent. It can also be described as a process of chipping away at or deconstructing layers of illusion collected by our immune system (or the system of thought) in order to protect the identification with the self it has constructed. This process can even be viewed as opening a window (letting the light in) into the experience of the virtuality of at least some small aspect of self.

---

[15] I avoid the term definition as I prefer not to get into all of the limitations and constraints I perceive as inherent in the concept and practice of defining terms.

Bringing this part of the discussion to an even sharper focus, what can be gained by reframing what we are subject to at the levels of the socialized and self-authoring mindsets? The fundamental self-deception and big assumption in the socialized mind might take the form of identification with social norms, forms and roles in society being taken as 'real' rather than constructed.[16] Peeling away one rather large layer like this enables the self-authoring mind to be the 'operating system' within the system of thought. Filtering incoming and outgoing information according to its own agenda enables a more complex and powerful stance in relation to the world. Yet Kegan and Lahey (2009) note that this improved, more complex version of the self "may also be a recipe for disaster if one's plan or stance is flawed in some way" (p. 19). Incoherence can strike with any level of complexity of mind. This points to the importance of having more coherent conceptions (or beliefs) as content being used within any order of consciousness. Peeling away the structure implicit in the self-authoring mind can lead to operating from what Kegan describes as the self-transforming mind,[17] yet the same issue of coherence of contents persists.[18]

Coherence can thus be partly understood in terms of structures of consciousness in that the higher orders of this have a more flexible relation to the contents of the system of thought. However, it is also clear that the contents of consciousness play a role in this at whatever order of consciousness we are operating from.[19] While complexity of meaning making will influence how we interpret the content of experience, the underlying and mostly implicit assumptions and worldview will also shape the content and how it is interpreted. At the same time, it has been noted that coherence also has to do with awareness as the experiential realization of the virtuality of self (and by extension and association, the virtuality of our perception of the world as a whole from within this virtual or identified self). This brings the discussion back full circle, to seeing the wisdom inherent in transcending the identification with self.

The discussion thus far has highlighted the new possibilities Bohm's and Arbinger's views bring to the immunity to change process. This centers on a fundamental choice for self-transcendence, or to use a belief, mental model etc. that is more coherent. The contents of this revolve around the virtuality of self and moving away from identification with self as a kind of ontologically real entity. The re-conceptualization of the construct *self* is essential to leverage our attempts to transform our immune systems. I now direct attention to the second focus of this article, the implications of this for leadership, its development and practices.

---

[16] This seems to make an easy and obvious connection to the central concepts of social constructionism (Gergen, 1994). Further links and thinking about how the findings and distinctions in this inquiry might inform social constructivism are for the future. As well, how these conceptions could inform our understanding of the self-transforming mind is also beyond the scope of this article.

[17] I have heard that the ITC process is not really designed so specifically for the transition from self-authoring to self-transforming. It would be interesting to see how utilizing the set of conceptions emerging from this inquiry could inform a process more targeted at that particular transition.

[18] Suanne Cook-Greuter (2010) eloquently addresses the misconceptions around presumed advantages of higher order structures of meaning making in themselves being sufficient for people to function well in society.

[19] As well, this is only examining this from the notion of using the construct of 'inner operating systems.' Fisher's (1980) dynamic skill theory can offer another conception to examine this from, but given this article's focus on Kegan and Lahey's immunity to change process, exploring that lens would be for another time.

What can this View of Awareness Contribute to Leadership Development?

The notion of the wisdom of self-transcendence has been described as fundamental in relation to (transformational) leadership (Carey, 1992). From this, what are the broader implications of this for leadership and its development as a whole? This is the question I turn to next. Here I revisit relevant aspects of the literature reviewed earlier, as well as other sources that appear relevant, to see what can be gained from applying the findings from this project to those ideas.

In terms of looking at awareness based practices as a concept for leadership development, the conception of awareness is now more clearly articulated as the experiential realization of the virtuality of self. This is related to the source of insight and a "creative notion of being" (Bohm, 1992, p. 169), or the light of being coming from others (Warner, 2001). This is in clear contrast to the functioning of the immune system/system of thought operating outside of awareness and generating a virtual self. The identification with this virtual self leads to self-deception and all that comes with it. From this, the concept of an awareness based approach to leadership development practices takes on a richer set of meanings and points to a deeply grounded sense of presence in a more coherent perception of events in life.

Developmental Implications

First of all, I note that there could be a further link worth exploring in relation to how Fisher's work on dynamic skill theory could be connected to, or utilized in relation to this notion of awareness as being outside of the immune system, or any constructed sense of self. Fisher's work never used the term ego, and in this sense, can be seen as somehow grounding itself, even if only implicitly, in this domain outside the system of thought. A future project could be to examine how tools built from Fisher's theory (Dawson et al., 2005; Dawson & Stein, 2011; Stein, Dawson, & Fischer, 2010), especially as related to leadership development skills,[20] could benefit from applying the conceptual view described here.

Next, it has already been noted that there are new possibilities in how to approach the immunity to change process. At the same time, there could be implications for ego development theories in general. If ego development is implicitly oriented towards building ever more complex capacities in a self that is inherently virtual, it is possible to imagine it being ever more challenging to master such constructions of self.[21] I do not view this as problematic in and of itself; simply that it invites consideration of how this complex, sophisticated and capable virtual self is kept operating in service, and not as the master. The implications of this for leadership are many. One consideration is how can a given population discern the subtle levels of fallacy and or incoherence that could creep into leadership coming from such a complex virtual self?

---

[20] In particular I am thinking about how to understand using the LDMA, or Lectica/Leadership Decision Making Assessment from Lectica.

[21] It is also possible to link this to Vaughan's (1995) (and others) notion of the inward arc, where we develop ego only to eventually transcend it.

Leadership Development

Day & Dragoni's (2015) review of leadership development research mentioned above identifies leadership self-efficacy, self-awareness and leader identity among the key indicators for leadership. It is easy to note that the first two items involve self and the third (of four in total) is about identity. In light of the present inquiry, it is worth taking a critical look at how those constructs are employed in leadership development work. While a thorough undertaking of this is for future projects, some initial considerations can be put forward.

First, Day and Dragoni use the term self-awareness, mixing the two key terms that came to be seen in contrast to each other in this project. Various sources cited in the literature review also note the term self-awareness as central to leadership competency. It was noted above in the discussion that how self-awareness is used in relation to leadership development does not generally address the distinction between self and awareness highlighted here. What might be useful in light of this is to reflect on how the construct of self-awareness is held by the tacit views apparent in such discourse. Is it a self that is aware of its own nature, or is it awareness that is proprioceptive of the virtuality of self? Can making the distinctions noted here between the two terms bring additional clarity or even coherence to the discourse on self-awareness in leadership?

Then what about self-efficacy? Given the distinctions made in this project, self-efficacy could be similar to how it is described above in relation to ego development; what if the self, with this fundamental incoherence limiting it, is so efficacious that it takes control and sees itself as the ultimate master of its world? This could lead to a subtle but deep flaw in how leadership is practiced, certainly a lack of humility. In light of notions of servant leadership (Greenleaf, 1977), seeing self as overly masterly could go against the grain of being of service to a larger sense of purpose. On the other hand, self-efficacy could be conceived in terms of awareness being efficacious in proprioceptively enabling the virtual self to be more and more coherent, and thus better able to serve a larger purpose.

Finally, the notion of an identified sense of being has been understood as a problematic orientation to how we conceive of our beingness in the world. Leadership identity could suffer a similar fate as the previous two constructs. It could lead to a type of self embeddedness which Carey (1992) described as a fundamental option, but one that leads away from the practice of leadership. The other fundamental option is for self-transcendence, which is viewed as the key to practicing transformational leadership. All of this points to the importance of making implicit views, or fundamental big assumptions, sufficiently explicit, at least in relation to this key area. How the construct of self is tacitly informing the lens through which we are viewing leadership is, from the present inquiry, viewed as critically important.

Above, I claimed that one aim for this article was to find how the conception of an awareness based practice could facilitate relevant developmental growth applicable for leadership. The question was raised above in relation to implications of the findings of this inquiry and the field of ego development theory as applied to leadership development. Here I want to breifly address some key points that I believe are worth examining. There are currently a number of ego development models that have been utilized for the purposes of leadership development.[22] (While I believe that many creators of these tools and frameworks are mindful of the distinctions I am foregrounding in this article, I am not sure of the degree to which the implications of the distinctions and view underlying them permeates the everyday application of these frameworks among the broader community of practice). Above, I described some possible implications of dealing with ever more complex constructs of a virtual self. It could be said that a primary focus of these models is very much on developing the very self that has been viewed as problematic. A response I noted above is that from the view arising here, the challenge is to keep in mind a kind of 'personal mastery' (Senge, 1990) that maintains awareness (or 'mindfulness') of the virtuality of this self that is becoming ever more complex (and thus ever better at hiding its own virtuality).

Mindfulness and the Presence of Awareness

This brings up the topic of mindfulness and its relationship to the kind of awareness discussed here. The brief survey of mindfulness presented above desribed both some early sources of this orientation for my own thinking as well as some recent approaches characterized under the conception of presencing (Scharmer, 2000, 2007; Senge et al., 2004). The critical (as well as appreciative) review I did of Scharmer's *Theory U* (Reams, 2007) highlighted what I perceived as some implicitly held limitations in the view behind how presencing was conceived. More recently Jaworski's *Source* (2012) also addressed the issue of what is at the bottom of the U, or if presencing as a concept is actually a gateway into a deeper experience. This deeper experience, in light of the present inquiry, can be conceived of as the awareness itself in the form of the experiential realization of the virtuality of self. As noted above during the exploration of Rowson and Varela's conceptions of this, maintating a degree of awareness is seen as the core of wisdom. Thus it is possible to think of mindfuness as maintaining awareness and realization of this virtuality, creating keeping the self in a coherent context or perspective.

This kind of mindful awareness is perceived as central to leadership. This notion is also found in the work of Chatterjee (1998), who states that "leadership is not a science or an art, it is a state of consciousness" (p. xix) and that "we can now begin to grasp the phenomenon of leadership as the field of awareness rather than a personality trait or mental attribute" (p. 24). Conceiving of leadership in this manner, given the rich set of associations and connotations that have been found here in relation to awareness, allows for a clear connection to the distinction made between awareness and self. Here there is the addition of the term field to awareness, giving a nuance that can be utilized further in this discussion.

---

[22] A brief survey I did recently for another purpose revealed a surprising number of instruments. Some were values based developmental models such as Brian Hall's, Richard Barrett's and the Spiral Dynamics work. Ego development tools included Bill Torbert's Global Leadership Profile, Susann Cook-Greuter's Leadership Maturity Framework and corresponding Maturity Assessment Profile, Terri O'Fallon's StAGES model, Otto Laske's Leadership Development Assessment and Bill Joiner's Changewise 360. Of course many consultants also use Kegan's subject object interview protocol to support leadership development work.

A field has properties that come from what can be conceived of as initial conditions.[23] These conditions are often stable, or not accessible to change without the capacity to directly perceive them. The effects of these initial conditions and the fields they create are also referred to in some discourses as culture in an organization, which is generally perceived as very difficult to produce meaningful changes in. This is visible in the phrase from Peter Drucker that *Culture Eats Strategy for Lunch* (Coffman & Sorenson, 2013). Owen (2000) talks about myth and storytelling in relation to culture and its transformation, pointing to the power that is available in a leader being able to shape the field or culture through the culture generating method of myth and storytelling. From this the ability to consciously (and coherently) perceive the initial conditions that generate these fields can be conceived as an act of leadership.

Central to this is the how "high-energy seeing enables you to touch events or persons with a quality of awareness" (Chatterjee, 1998, p. 3). The quality of awareness referred to by Chatterjee can be interpreted here as the kind of self-transcendent, coherent and insight generating creative conception of being that came from the findings of this inquiry.[24] This is further exemplified by Chatterjee saying that "there comes a time when an individual becomes irresistible and his action becomes all pervasive in its effect. This comes when he reduces himself to zero" (p. 51). This reduction of self to zero is the ultimate self-transcendence, a move away from being identified with not only a self, but any of the roles or even objects that become centers of identification.

Concluding Reflections

Here, near the end of the journey of this project and article, I find it useful to look back and try to summarize what has come from this inquiry. First, what can be said about the ITC process? The concept of overcoming our immunity to change has been examined by analyzing how two other lenses on this phenomenon can add nuance and distinctions. Given that big assumptions play a critical role in the ITC process as described by Kegan and Lahey, it is clear that the content of our beliefs and making them more coherent is central to success in this. The inquiry undertaken here focused on how the identification with self is held to be the central assumption limiting change. If we are embedded in an identified sense of self, we fall prey to a fundamental self-deception which darkens our perception of the world and leads to all manner of self-justification that creates the problematic challenges in our lives. We end up living outside of awareness in the immune system's constructed representations of reality.

The antidote for this darkness or incoherence of perception is taken to be awareness, the *experiential realization of the virtuality of this self*. This is awareness as distinct from the system of thought and generating insight which can bring greater coherence. Achieving and holding this view is tied to being open to acting on the impulses for action arising in us from attending to the light of humanity coming from others. The immunity to change is thus rooted in self-embeddedness, and its cure is found in self-transcendence.

---

[23] There is of course a well-developed discourse on how field theory can be applied to leadership that I am only briefly touching on here. For one of the more influential descriptions of this, see Wheatley (1992).

[24] This can also be thought of in terms of quality of presence (Reams & Caspari, 2012).

Then what about leadership development? Self-transcendence is also seen as key to leadership, and is found in such popular conceptions as servant leadership. It is also apparent from this inquiry that reconsidering the construct of self-awareness in relation to leadership can be a fruitful area to explore further. Viewing awareness as the proprioceptive perception of the virtuality of self, enabling (through insight) the virtual self to be more coherent, can provide a key for leadership.

The degree of this awareness present in leaders/leadership contributes to the overall quality of presence through the field of greater coherence it generates. This field of awareness can be seen as the deepest level of functioning of leaders/leadership, enabling others to engage in this process of using the events of life and work to foster their own and their organization's as well as societies' growth towards coherence. Leadership in this sense consists of the choice to attend to the light coming from others and engaging practices that support this.

The larger aim of this project has been to lay a foundation for understanding *awareness based practices for leadership development*. While thoroughly applying the conceptions arising from this inquiry to a variety of aspects of leadership development is for future projects, some groundwork has been laid here. How awareness is conceived and distinguished from self helps to clarify what has been conflated, implicit or unclear previously. The wisdom in proposing the virtuality of self also provides a foundational conception for going forward. The understanding that the experiential field of this awareness generates spaces that can give a sense of purpose and alignment to others provides a direction for focusing development work in leadership.

Limitations and Benefits

Given what has been put forward here, there are some clear limitations to this article. The *feeling into a view* presented here is both enhanced and biased by my own experience of the virtuality of self.[25] At the same time, this is the phenomenological lens that has emerged for me from the re-hardwiring of the system of thought that this experience generated. Thus the implicit lens (that I have worked to make as explicit as possible above) used here in a sense limits this work to first person validity.

At the same time, the use of methodological processes to work through the textual accounts of what are perceived as related views of a similar phenomenon has been aided by the possibility that this tacit view could act as a tuning fork, to guide me in the selection of text to analyze as well as in helping me bring an appreciative interpretation that could open up possibilities from making this tacitness more explicit. It is up to each reader to determine the degree to and or areas in which the views put forward in this article resonate, or give voice to some tacit knowing.

As well, this project was intentionally limited to drawing on a few sources chosen for their personal interest and perceived relevance to the topic. I did not draw on Kegan and Lahey's (2001) earlier work on the immunity to change process. I also neglected to utilize various writings by David Bohm on the topics of implicate order and dialogue (1980, 1996). While I suspect that a more thorough analysis including these texts could have enriched the project, I also suspect that the outcomes might not have varied so much, as I had a sense of saturation of the relevant themes from the texts used here.[26]

---

[25] This came up in the course of my conversation with Jonathan Rowson (Reams & Rowson, 2015).

In the end I make no clear claims of empirical certainty from this project. I simply offer an explication of this view, aided by whatever degree of rigor I could bring to bear through the method, to a subject matter that has generated a significant interest.

Reflections

My first venture into the world of academic writing (Reams, 1999) asked the question "who do we think we are?" This subtitle was intended to imply that the self that thought constructs is not 'who we are' in reality.[27] As I stated above, it is clear that there is a deeply tacit view around this that I have been working to articulate throughout the part of my life that has found an outlet in academic life. The application of this view to leadership development has also guided the direction of my work. This article is another step along that journey.

I see that most of what I have done here is simply to make more explicit something that is in many ways obvious and apparent, at least given a deep sense of a tacit view that I perceive as having some degree of coherence. In aiming to unpack the distinctions here around awareness based practices for leadership development, my goal has been to bring these out for a more detailed examination. My hope has been that this will first of all build some basic foundational pieces for future work in this area. It is also a hope that this project will provide a basis from which to further unpack implications of extending the view these distinctions arise from in relation to other aspects of leadership and its development.

[26] I am also painfully aware of a rich set of texts highly relevant to this project that have been (as described above) bracketed to the side for the sake of being able to do at least this much. Notes are piling up in relation to many of those, as well as many more I know are possible to engage. At the same time, it is clear that a very different and contrasting or contradictory set of texts, data and research results could be taken into such a project to bring a more diverse or balanced orientation to the worldviews or paradigms engaged here. All of these contribute to the limitations of this work.

[27] While it is beyond the scope of the present article, the answer given to the question was simply soul. I later gave a definition of soul as a "*creative unit of pure awareness*" (Reams, 2012, p. 104, italics in the original). More recently I had the opportunity to interview Jonathan Rowson (Reams & Rowson, 2105) and we had a lively discussion on revitalizing the use of the term soul in public discourse.

Appendix I: Methodological Considerations

There are various ways in which I can categorize my sense of the methodological background that I have utilized in doing this work. In this appendix I will primarily address the main considerations behind my approach to and preparations for the project.

The notion of bricolage might be the best starting place. Rowson (2008) notes that a bricoleur or "handyman" (p. 127) is well suited to address methodological issues raised in a post-positivist, socially construct aware research culture. His realization that the notion of 'findings' are less relevant "because on this sort of topic [wisdom] there is nothing to be credibly 'found'" (p. 128) leads me to articulate that my goal is less to show findings in an empirical sense and more to reveal a sense of feeling into a view (although there are components of both intertwined). This can be linked to Gadamer's (1993) perception that "all understanding is ultimately self-understanding" (p. 260) indicating a need to have a strong heuristic (Moustakas, 1990) component in the mix. Thus in the methodological considerations for this research I draw on a range of handyman tools; [28] methodological components chosen as perceived to best fit with the different phases, components and needs of the research project.

Gidley (2007) cites Denizen and Lincoln (2005) in describing a bricoleur-theorist as one who "works between and within competing and overlapping perspectives and paradigms" (Gidley, 2007, p. 6). The tensions and challenges inherent in moving beyond disciplinary approaches towards transdisciplinary ones can be described in terms of complexity of cognition and "the epistemological structure of interdisciplinary validity claims" (Stein, 2007, p. 91). Thus working between and within competing and overlapping perspectives and paradigms requires adequate cognitive complexity to take perspectives on those tensions. It also demands sensitivity to level of analysis issues, or what I like to call attending to the 'domain of validity' of a given aspect of the inquiry at hand. It is in this sense that I find a bricoleur approach that enables the use of domain appropriate methods in a sensitive manner best suited to the current undertaking.

I am also mindful of the difficulties in accomplishing this with a substantial degree of transferable recognition among a community of those who are an ongoing part of this discourse. In addition, given that an explicit aim of this work is to begin establishing theoretical foundations for developing an understanding of awareness based practices for leadership development, there is a wish for this work to also speak in an intelligible way to a broader audience possibly unfamiliar with some aspects of the territory covered here. Thus I aim to navigate between a complex and critical inquiry into this view and an articulation of it that meets a reasonable demand of general intelligibility.

Given these orienting perspectives, I will now delve into the more specific and substantive issues appropriate within each methodological tool in my tool belt.

---

[28] I find this notion of bricoleur as handyman especially appealing. It enables me to draw on other aspects of my life experience as a way of understanding how a handyman works with different tools and trades to do things. Having a farming, construction and truck driving background, I have a very embodied sense of how to be able to do a bit of everything necessary in a given context.

Metatheory

There is a clear sense in which this work falls into the category of metatheoretical research given that I am using the texts and theories of others as my primary source of data. My respect for the work of Mark Edwards (2010) in this field is documented elsewhere (Reams, 2011). Here I want to acknowledge and draw on elements of this approach I perceive as appropriate, without laying claim to doing rigorous metatheoretical work. In a rigorous metatheoretical method, Edwards would include: groundwork, domain specification, design, multiparadigm review, multiparadigm analysis, metatheory building, implications, and evaluation. I will briefly outline how I have or have not addressed these.

For the groundwork aspect of this I can draw on decades of personal practice and inquiry into consciousness and awareness oriented practices and academic inquiry into consciousness studies and leadership studies. I also described in the introduction how I am focusing on the domain of awareness based practices for leadership development using ITC as a leading exemplar, providing a degree of domain specification.

The design of the project within the domain specified is that I took literature from three sources and engaged in a textual analysis of elements that meet criteria I will lay out in the methodology section (Kegan and Lahey's (2009) Immunity to Change, David Bohm's (1992) Thought as a System, and the work of the Arbinger Institute (1997, 2006, 2010; Warner, 2001)). To a degree this diversity of focus sources addresses the call for a multiparadigm review, although the boundedness also clearly puts limitations on how well this step is addressed. These three primary foci will be partially supplemented in the discussion with relevant insights from other fields that are deemed pertinent to shed light on aspects of this project. These additional sources might also be considered to come from diverse paradigms, helping better address this component. [29] The aspect of multiparadigm analysis is part of the design in so far as the outputs from the textual analyses are presented.

Metatheory building was then undertaken in the specified domain. This happened primarily by weaving the threads provided by the three theoretical lenses to find common themes as well as important distinctions and how those influence thinking about ITC in particular. The implications of this are linked to relevant literature. Finally, some brief evaluative reflections on the outcomes of the process are undertaken. In this limited manner I have aimed to bring a metatheoretical methodology to bear on this project.

Heuristic Inquiry

The nature of this research is such that it involves a good deal of 'self as instrument' in that as a researcher I was holding the question of inquiry while noticing and reflecting on my subjective experiences as I engaged in reading the various texts that are the focus of this project. In the background phase, I had some unarticulated felt sense of what this notion of awareness based practices for leadership development are, and of what each construct is about. This comes from my prior immersion in various experiences, reflections on them and trying to make meaning by connecting them to language and meaning I encounter in a variety of communities of discourse. There was also a phase of probing and testing for the utility of emergent ideas in various settings to see if the meanings forming bear up in different conditions and contexts. All of this points to drawing on heuristic inquiry as an aspect of the methodology.

---

[29] The intention to build on this work in the future by engaging a broader range of relevant theory places the current article within the context of a longer term research and publication agenda.

Moustakas (1990) tells how “underlying all other concepts in heuristic research, at the base of all heuristic discovery, is the power of revelation in tacit knowing” (p. 20). Tacit knowledge is described by Polanyi (1983) simply as “we know more than we can tell” (p. 4). It also “is personal knowledge embedded in individual experience and involves individual factors such as personal belief, perspective, and the value system” (Nonaka & Takeuchi, 1995, p. viii). Heuristic inquiry utilizes a combination of the subsidiary and focal elements of tacit knowledge. The subsidiary factors include those elements of experience that stand out in examination and attract immediate attention, are visible, part of conscious awareness, and can be described. The focal elements include the unseen and invisible, and make possible access to the wholeness of the phenomenon. The combination of elements facilitates the researcher’s task of making tacit knowledge of the subject explicit and communicable.

In this project, part of the method or procedure used was for me to notice what stood out for me when reading the texts, being sensitive to how the perceived meaning in and between the lines lit up, or connected with some of the tacit knowing that I held as a sort of tuning fork. Using this criterion I had a means by which I could select elements of text from the whole. The main challenge was to maintain a degree of focus and mindfulness of my inner state while reading to keep the sensitivity to this ‘tuning fork’ quality in the foreground. I held this notion of my tacit understanding as a way to conceptualize the criteria by which I chose statements to highlight and analyze.

My approach to this was informed by the concept of adequatio, or that “the understanding of the knower must be adequate to the thing to be known” (Palmer, 1993, p. 51). Similarly, Braud and Anderson (1998) note that “we can perceive and know only that for which our sensitivities have prepared us, and these sensitivities depend on aspects of our being” (p. 22). Osborne (1993) states that “we cannot inductively derive an essence from examples unless we can already intuit that essence” (p.171). In this manner I perceive the ongoing heuristic inquiry component of the project to be a kind of dialogue between my evolving tacit and explicit (Nonaka & Takeuchi, 1995) knowledge with the texts and phenomenon encountered through experience. I conceive this in terms of a kind of ‘dynamic steering’[30] where with each data point, clue, or piece of the puzzle, I made some form of course correction that helped navigate towards the subject of inquiry.

Hermeneutics

Using the texts of three sources as the basis for this work implies that within this bricoleur approach the element of textual content analysis is the most visible, tangible component of the methodology. Closely related to this is the use of a hermeneutic orientation, being explicit about how I am interpreting the texts in view. Gidley (2007) outlines a four quadrant description of Ricoeur's (1986) approach to hermeneutics from which I draw on the notions of the autonomy of the text itself (in that it stands for something), this in relation to the socio-cultural backdrop it was written in and with an eye to the intentions of the author (or trying to read between the lines into what is tacit in the author's view). This hermeneutical approach to textual interpretation is of course grounded in the lenses available and chosen for this work. This depends on the heuristic aspects described above.

---

[30] I am borrowing this term from my encounter with the practice of Holocracy.

One of the choices I faced was how to navigate the tension between a hermeneutics of suspicion (Ricoeur, 1986) or of a rational analytical "demystification" (Palmer, 1969, p. 44) of the text and a demythologizing, which "deals lovingly with the symbol in an effort to recover meaning hidden in it" (ibid. p. 44). While my preference is for the latter, leaning on an appreciative reading of the texts, I recognized the need to draw on a critical, rational analytical eye from time to time.

Palmer (1969) points to a mode of understanding more fundamental than rational analysis. This can also be seen in relation to Nonaka and Takeuchi's (1995) conception of tacit knowledge, or Gadamer's (1993) prejudice or the hermeneutical horizon of our preunderstanding. It also points to a conception of a 'trans-rational' mode of knowledge (Reams, 2002), in that the analytical function of rationality is secondary and where the notion of 'defining' the focus of inquiry is considered to be 'unwise' (Rowson, 2008). It is in this sense that I aim to uncover, illuminate and describe what I perceive as emerging from this inquiry.

Appendix II

Node generation results based on weighted percentages. (Most relevant results only).

Appendix III

Table of Theme Summaries

Theme	Kegan and Lahey	Bohm	Arbinger
Self	Notion of self as entity that is identity, tells a story and protects itself.	Concept of self is linked primarily to incoherence or illusion.	Conceptions of self related to underlying root cause of betrayal, deception, justification.
Conscious	Primarily as conscious of self in relation to various aspects; identity, narrative, protective.	Linked to either being aware and learning or of being deceived and not conscious.	Notions of asserting a fictional self and deception and betrayal.
Immune	Central concept, both as an intelligent force that resists change and can be overcome and change into a bigger and more complex system.	No direct mention.	No direct mention.
System	System occurs first as an immune, defense, anxiety management system. System occurs second as a mindset or intelligent force that can become bigger and more complicated.	System is in relation to how thought is conceived, a single set of reflexes including thinking, thoughts, feelings, felts.	Not mentioned in text.
Others	Opinions we need to defend against.	Helping.	Two main themes, around either resisting, accusing, blaming or diminishing others, or a mutual response to the light in others to enable change.
Feelings	Feelings as being intricately inherent in the problem, forming an ecology that resists change.	Feelings as part of the set of reflexes making up the system of thought.	Feelings as untrustworthy, justifying, misleading us. Also feeling related to generosity of spirit.
Change	Change conceived as mental development, changes in structures, developmental shifts i.e. subject / object, altering theories in use.	Change as modifying reflexes, electrochemical, perception. Also as deception or moving away from awareness.	Change conceived as both self-betrayal, shifting blame, taking offense and being open, affected by the light of others, responsive to truth, fundamental change of heart.

Make	Make generalizes into several concepts; creating things like anxiety management systems, warning systems, false beliefs, blind spots, constraining action, actively preventing change. Also a process of developmental shifting.	Make shows up in relation to reflexes producing thought, separation and self-deception, unawareness / insensitivity, changes in perception, making traces and false information, affecting and determining action.	Make as resisting what we have created, accusation and making wrong appear right, making justifications and projections. Also as making clear distinctions, allowing others influence, becoming receptive to truth.
Thought	Thought as meaning making, assumptions, opinions. Also as a warning system.	Multiple conceptions; as the source of problems, deceptive, participating but hiding assumptions, giving false information and affecting perception. As a set of reflexes that automatically control, resist and defend. Identity as incoherence, creative perception and being, insights and truth, coherence (detachment).	Thought as perception, judgment, understanding. Insight as notion of truth. Anxiety and resistance. Heart, change and peace, character.
Cognitive	Cognitive in relation to structure, mindset, intelligent force. As creating reality. Insights and respectful stance. Insufficient for change, creating blind spots	Thought as a system, active, probing set of reflexes. Coherence and incoherence. Deception, resistance to insight, forgetting, participating. Produces an ‘I’. Insight, coherent perception, unconditioned capacity, creative being, perception of truth.	Subtle and pervasive self-preservation, resistance of truth. Making and believing judgments. Insecurity about filtered perception and moral sense, process of justification. Heart at peace, affected by the light from others, love, insight, discernment, responsive to truth, forgiving.

Appendix IV: Key Themes Illustrated

This appendix is (mostly) made up of one paragraph describing the summary of each theme (related to the table in Appendix III) with varying amounts of quotes used to illustrate the use of these terms and provide a rich picture of key elements to be woven together. The order was decided by contemplating on the nature of each term and how I perceived the best narrative to unfold. Thus the ten terms are ordered first in relation to the concepts that seemed most obvious as well as those that were not as richly utilized, saving the less obvious and more referenced ones for later (these came mainly from the specialization and generalization query results).

Self

I began with examining how the concept of *self* was used. First, implicit in how I perceived Kegan and Lahey's use of self was that they appear to treat the construct of self as a given, an identity or 'entity.' While this can be considered as a common or popular view in relation to the term, making this explicit here is important. This is because both Bohm and Arbinger utilize the construct of self in relation to terms like illusion, incoherence or the root cause of betrayal, deception and justification, implying a fundamentally different view.

Kegan and Lahey talk about how someone "gradually rewrites the self-narrative" (p. 133) and how criteria for a good entry in column three of the ITC process "is that it is self-protective" (p. 150). Bohm writes about how we are conditioned to resist seeing how thought is "infusing our imagination, our past, our knowledge into what we see" by itself and "that's really where the self-deception arises" (p. 161). In terms of creating an image of self, he writes that "the system contains a reflex which produces the thought that it is *I* who am doing everything" (p. 92). This eventually works into the conception of having "the notion of a creative being, rather than an identified being" (p. 169). For Arbinger, is it clear that self is also linked to how "we cannot doubt that our judgment is true" (1997, p. 4) and this becomes so entwined in us that "self-deception permeates experience" (p. 5). Arbinger even goes so far as to say that the self-betrayal that is the root of self-deception creates a "virtual reality, the product of the technology of defense inevitably employed by self-betrayers" (p. 9).

Conscious

When looking at the term *conscious*, it is used in similar ways as self is for Kegan and Lahey, as in being conscious of self in relation to identity, narrative and being protective. For Bohm it is used more as a distinction between being aware and learning or of not being aware and being deceived. For Arbinger, it occurs around notions of asserting a fictional self and from that again linked to deception and betrayal.

Kegan and Lahey also talk about not being consciously aware: "Though you are not aware of it, you have created a very effective anxiety-management system … But neither of them experiences this anxiety consciously or constantly because the immune system is working beautifully to manage it automatically" (p. 48).

Bohm writes that: “We are producing these situations contrary to our conscious intentions because there is another resistance going on of which we’re not very conscious” (p. 11) which sounds very much like the description of immunity to change Kegan and Lahey use. Bohm also describes a type of resistance coming from the system of thought that avoids any unpleasantness and “is set up to move away from awareness of that” (p. 34). To counter this he proposes a stance where “we don’t try to do anything. We’re just learning – aware, attentive, learning” (p. 84), again sounding a lot like the ITC process.

For Arbinger, the assertion of this fictional self is described as; “constant self-assertion equals constant anxiety equals constant resistance” (1997, p. 6). The remedy or antidote for this is expressed clearly. “Self-betrayers do not comprehend that what they need is the destruction of this fictional self. … The phony self-image must die in order that they, as sensitive human beings, might live” (Warner, 2001, p. 77). Thus the notion of being conscious is somehow connected to being aware of and noticing the automatic operation of the fictional self to enable something more than self as a self-image to live.

Immune

Immune was the term that came up the least in the queries (see Appendix 1), however I wanted to include it because of its central place in Kegan and Lahey’s concept of immunity to change that is a focus of this project. For them it is used in relation to notions of an intelligent force that while it resists change, can be overcome. It can also change into a bigger and more complex immune system. Bohm and Arbinger did not mention it.

Kegan and Lahey note that like this intelligent force, the immune system in our physical bodies is trained to reject new material. Sometimes “the body needs to heal itself or to thrive, [and] the immune system can put us in danger. In these instances the immune system is no less focused on protecting us. It is just making a mistake” (p. 37). In response to this, they do not see a need to eliminate our psychological immune systems. “The solution … lies in transforming this immune system, in building a bigger and more complicated immune system” (p. 49). In this sense immune is used as a direct analogy between how our physical bodies function and how our emotional or psychological bodies function.

System

Kegan and Lahey use the term *system* in two ways, first in relation to the notion of an immune system, characterized as a defense or anxiety management system. Second, they talk about it as a mindset or intelligent force which can gain in complexity and size. For Bohm, system is part of how thought is conceived, as a single set of reflexes (described in more detail in the section on thought). Arbinger does not refer to the term system in the text excerpts I had noted.

Kegan and Lahey write “that every immune system is an intelligent force that seeks to protect you, even to save your life” (p. 47). The key to growth for them “lies in transforming this immune system, in building a bigger and more complicated immune system” (p. 49). Bohm’s use of the term is quite broad, using it to say “that system not only includes thoughts, ‘felts’ and feelings, but it includes the state of the body; it includes the whole of society” (p. 19).

Others

All of the previous terms resulting from the queries were expected given the nature of the literature and focus of my extracting quotes from these sources. The term *others* was less anticipated. This was shown in that Kegan and Lahey primarily use the term in relation to self-protection, or defending ourselves from others opinions. Bohm only mentioned others in terms of helping others by sustaining dialogue. For Arbinger, the conception of others occurred in relation to two main themes. One was related to resisting, accusing, blaming and even diminishing others. The second was in relation to mutuality and responding to the light in others to enable change.

Kegan and Lahey talk about this self-protection as being "about protecting or defending the self we want others to see, or the way we want to see ourselves" (p. 150). Bohm notes that "once you have an insight into this, sustaining the dialogue in yourself will help the others" (p. 208). However for Arbinger, the notion of other plays a much more important role. For example, in the state of self-betrayal with others, "together we create and reinforce for one another the self-deceived reality in which we each feel unfairly treated, and each are convinced that we alone are completely justified" (1997, p. 9). In addressing our way of being they note "the deepest way in which we are right or wrong … is in our *way of being* toward others" (2006, p. 57, italics in the original). In relation to how we can make changes in this, they note that "*to the extent that we can come to see others differently, we can undergo a fundamental change, a change in our being, a change of our emotions and attitudes, a change of heart*" (Warner, 2001, p. 46, italics in the original). This change of heart is enabled by us being able to let "*ourselves be affected by the light coming from others, or, in other words, the truth concerning what they are feeling*" (p. 151, italics in the original). This is very much linked to taking an I-Thou (Buber, 1958) orientation to others.

Feelings

Kegan and Lahey approach *feelings* as a central part of the ecology of our immune systems that resist change. Bohm sees feelings as another facet of the set of reflexes that make up the system of thought and can lead to a feeling of necessity. For Arbinger, there appear to be two themes; one around feelings as justifying, misleading and untrustworthy, while the other is around a generosity of spirit.

Kegan and Lahey note that in order to make a successful immunity to change map, it is critical that our improvement goals are not merely rational, but that "we must also experience sufficient need or desire, visceral feelings" (p. 210) in order to "connect head, heart, thinking and feeling" (p. 31). Bohm describes how "feelings are tremendously affected by thoughts. And obviously thoughts are tremendously affected by feelings" (p. 7). This interconnectedness is also visible in the power of the feeling and "thought of necessity. It is much more than a thought. The word 'necessity' means 'it cannot be otherwise,' and the Latin root means 'don't yield'" (p. 68). Thus the resistance that has been described elsewhere can be linked to this feeling of necessity.

For Arbinger, feelings have this polarity of deception or liberation. On the one hand, "self-betrayers truly do have their accusing, self-excusing feelings. But this does not mean that the feelings themselves are truthful" (Warner, 2001, p. 31). In this state of self-betrayal and not being truthful, these feelings can deceive us and "our moral sense or conscience becomes untrustworthy" (p. 110). Yet on the other hand, "a correct understanding of why we feel and think and act as we do helps to set us free" (p. xii). The key then is in the correct understanding, or as noted below, can be thought of as coherence.

Change

For Kegan and Lahey, *change* is conceived as mental development or changes in structures of meaning making or the altering of theories in use. For Bohm it is about modifying reflexes, electrochemical changes in the brain and perception, as well as deception and moving away from awareness. Arbinger again has a twofold use; one in relation to self-betrayal and shifting blame and the other is around being open to being affected by and responsive to the light in others, leading to a fundamental change of heart.

The changes in the structure of meaning making Kegan and Lahey describe are not simply additive, but for them development is transformative. "This means that if we want to increase mental complexity, we need to move aspects of our meaning-making from subject to object, to alter our mindset" (p. 51). As well, the notion of immunity in relation to change means that "we are actively preventing the very change we wish to make" (p. 56).

Bohm also noted this resistance in relation to change, as in when we encounter unpleasantness and there is a move away from awareness of it. This resistance is linked to the notion of identity; "because that gets in the way of the need to change our reflexes. Once we identify with something, our reflexes are that way – it's very important, 'necessary'" (p. 167).

Arbinger note that "we resist changing the very emotions that make us miserable" because "these emotions and attitudes are accusing and inherently dishonest – and for this reason they are intrinsically resistant" (1997, p. 9). Echoing Bohm about how thought enters perception and then denies it, Arbinger state that "we participate in the creation of our emotional troubles and deny we've had any part in it" (Warner, 2001, pp. ix-x). They then point out that the "truth is, we change in the moment we cease resisting what is outside our box – others" (2010, p. 145). Above it was noted that this is connected to allowing ourselves to be affected by the light coming from others. It also comes down to a choice and following through on it.

Make

Make is a term I had not anticipated coming up in this list. However, it showed up as I queried stemmed words and at the synonym level it was the highest on the list. It turns out to be a very rich construct in this investigation. For Kegan and Lahey it generalized into concepts such as creating anxiety management systems, false beliefs and blind spots. It also was seen in relation to actively preventing change and as a process of developmental shifting. For Bohm, it showed up in relation to reflexes producing thought as well as in the process of separation, self-deception and unawareness. This was also around changes in perception that affected and determined action. For Arbinger, make was used in relation to resisting what we have created; making justifications that make wrong appear to be right, or making projections. However it was also used in relation to making distinctions and allowing others to influence us and becoming receptive to truth.

Kegan and Lahey see that they are "as it were, seeking to describe the structure of each way of meaning-making, why it created the reality it did" (p. x). Thus there is a creative activity going on. It also is clear that "you have created a very effective anxiety-management system" (p. 48), in the form of an immune system which "has been giving us relief from anxiety while creating a false belief that many things are impossible for us to do – things that are in fact completely possible for us to do!" (p. 50). Then this immune system inevitably creates "blind spots" (p. 48).

One of the central propositions in Bohm's view is related to how the set of reflexes, or system of thought, fundamentally deceives us.

> Thought runs you. Thought, however, gives the false information that you are running it, that you are the one who controls thought, whereas actually thought is the one which controls each of us. … That's the difficulty. Thought is participating and then saying it's not participating. (p. 5)

As well, "*thought is affecting what you see*. The representation enters into the perception." (p. 110, italics in the original). Related to Kegan and Lahey's notion of how our immune system keeps us acting against our best intentions, Bohm notes, "we don't realize that it is our deeper, hidden intentions which have produced it, and consequently we keep on perpetuating the problem" (p. 12). The antidote to this is gaining some perception by making things explicit; "whereas if you don't make it explicit you can't see that thought is involved at all" (p. 82).

For Arbinger, "to have that attitude is to be making and believing that judgment" (1997, p. 3) and that "we create what we resist by resisting it" (p. 6). However, like Bohm points out, thought moves us away from awareness of this, as it is uncomfortable. For Arbinger the outcome of this is that "we live a lie. This self-justifying lie takes the form of an accusation" (p. 8). The self-justification comes from self-betrayal, which together create a "virtual reality, the product of the technology of defense inevitably employed by self-betrayers" (p. 9). Yet not all is so depressing.

Warner (2001) notes that in order to answer these questions "we must draw a clear distinction between the light, or source of our understanding of right and wrong, and conscience" (p. 133). This light "continues always to stream toward us from the faces and voices and gestures of others" (p. 133) while conscience is one of our faculties that can be deceived. "To the degree that we become receptive and responsive to truth, life will keep instructing us" (p. 321).

Thought

Thought showed up in Kegan and Lahey's text excerpts in relation to meaning making, assumptions and opinions, as well as a kind of warning system. For Bohm it is of course a central construct. He uses thought in relation to being the source of problems, deceptive, and affecting perception. It is also described as an automatic set of reflexes that control the system, resisting change and defending itself. He also uses it in relation to the concept of coherence (related to insights and truth) and incoherence (related to participating in creating assumptions but hiding that participation). Arbinger uses thought in relation to constructs such as perception, judgment and understanding. They also see it in relation to insight as a notion of truth. Finally, they also use it in relation to a change of heart, peace and character.

Kegan and Lahey point to the need to get beyond thinking to shift our immune system. "We can't merely think or feel our way out of an immune system no matter how high our motivation is to accomplish our goal" (p. 217). They also imply something other than thought for this. "They all become keen observers of their own thoughts, emotions, and behaviors, and they learn to use these as information" (p. 244).

Some of the key constructs around thought for Bohm are described in the previous sections. Here I wish to focus on a more specific aspect, coherence of thought.

> The criterion for coherent thought is that it is true and correct. But if you can get pleasure or pain from thought then coherent thought is no longer functioning. Rather, the criterion has become whether the thought gives pleasure or pain, consequently that thought becomes destructive. If thought can be determined by pleasure or pain, that's already the beginning of a lot of trouble. (p. 49)

This is reiterated in the phrase "it can deceive us about anything and everything. There is no limit to its power of deception" (p. 99). As well, there are layers of incoherence involved. "We're saying that there is a second order of incoherence which avoids facing the first order; this second order avoids facing evidence of incoherence" (p. 63). This deception comes from unawareness of thought's participation in perception. It is Bohm's conception of insight that is perceived to have the possibility of remedying this unawareness. "An insight or perception of truth may deeply affect the material processes, which includes all of the reflexes" (p. 148). The result of this unconditioned insight is that "freedom is the creative perception of a new order of necessity" (p. 220).

For Arbinger, "often we call our sense of right and wrong conscience, though that name doesn't capture the way it arises from our living connection with other beings" (Warner, 2001, p. 21). Yet in the state of self-betrayal, we lose this connection and "in the darkness of our self-absorbed, suspicious thoughts and feelings, we cannot discern the way forward" (pp. 110-11). The remedy is described as a change of heart. "But even at its most profound, the change of mind and heart amounts only to a beginning" (p. 245). What follows from this is described in terms of forgoing. "If forgiving can be thought of as recovery from moral and emotional illness by means of a change of heart, forgoing is never falling morally and emotionally ill in the first place, never needing a change of heart" (p. 302).

Cognitive

The final of the ten terms coded was *cognitive*, which turned out to have the most uses when at the level of specializations and generalizations (495). Kegan and Lahey use the term in connection with structure, mindset and an intelligent force. They also connected it with creating reality and insights, but talked about it as insufficient for change and creating blind spots.

Bohm's use was connected tightly to the notion of thought as a system, an active, probing set of reflexes. It was also linked to coherence (now also as unconditioned capacity, creative being and the perception of truth) and incoherence (deception, producing an "I" and resistance to insight). Arbinger linked cognitive to; a subtle and pervasive self-preservation, resistance to truth, making and believing judgments, filtered perception and moral sense and justification. They also used cognitive in a different sense, in relation to; having a heart at peace, being affected by the light from others, insight, forgiving, discernment and being responsive to truth.

Many of the textual quotes relevant here are also represented above in relation to other terms. What stands out here is how Kegan and Lahey note that "we build an immune system to save our lives" (p. 50) and yet "we can't merely think or feel our way out of an immune system no matter how high our motivation is to accomplish our goal" (p. 217). They point to the need for "changing both their mindset … and their behavior; rather than changing only mindset or behavior" (p. 224).

For Bohm, many of the key quotes above are relevant here as well. However, he does describe cognition in a manner that illustrates the system perspective on how our 'immune system' resists change. In relation to moving away from pain or towards pleasure, he describes how:

> Now, by inference – by just thinking about it clearly – we can see that it makes no sense to keep on doing that and the result must be a real disaster. We could say 'my intention is not to do it.' But you will still find yourself doing it. You have a resistance coming from something else – from *the system*. (p. 34)

This resistance to change appears to us as necessary, and so we 'justify' or rationalize our actions. It is also connected to the notion of necessity quoted above in relation to feelings. All of this is described in relation to "some electrochemical process in the brain that preceded your conscious intention. The impulse is coming from the whole system" (p. 72). Becoming proprioceptively aware of the system of thought in operation can lead to "an insight or perception that this is true" and that "an insight or perception of truth may deeply affect the material processes, which includes all of the reflexes" (p. 148). All of this points to the need for an awareness of cognition, thought, perception etc.

For Arbinger, how the construct *cognitive* functions is described in this sentence about what happened to the author when succumbing to self-betrayal. "Having violated this truth [the basic call of his humanity upon me], my entire perception now raced to make me justified" (2006, p. 94) and "*My belief in my 'goodness' depends upon my belief in someone else's 'badness'*" (Warner, 2001, p. 63, italics in the original). Inquiring into the roots of this self-betrayal process and all that comes from it, the critical choice point is identified.

> So the choice that can change our hearts is not a choice of either our behavior or feelings. The first does not affect our way of being and the second, which tries to affect our way of being, is impossible. … The choice point comes elsewhere. It comes when we decide or not to yield to the truth about ourselves, about others, or about what's required of us and be guided by it in our actions. (p. 235)

This truth can then be seen. “We cleanse ourselves of insecurity and gain self-assurance when we do exactly as this love dictates, rather than constantly struggle to prop up a dubious, idealized image of ourselves” (p. 318).

This is a summary of the key points in these texts that have arisen through the various layers of the methodological process described in the methodology section. It is neither comprehensive nor exhaustive, yet my hope is that through providing a rich picture of the core points of these texts, it will be clearer how the threads extracted and woven together in the findings point towards an emerging description of an awareness based understanding of the immunity to change process.

On the Archetypes Hermes & Hestia: Notes toward a Hermeneutics of Leadership Studies

Nathan Harter[1]

In 1995, both James Hillman and Charles Handy published books about leadership in which they used the imagery of archetypes or “gods” to describe types of leadership. Handy, for example, wrote about Zeus, Apollo, Athena, and Dionysus. Since then, other authors with an interest in leadership have turned to the language of archetypes, including Carol Pearson, whose books avoid naming the archetypes as gods, but instead use more generic personifications, such as the Warrior, the Sage, and the Magician (e.g. Pearson, 2001). Recently, Mark Chater (2005), Neil Remington Abramson (2007), and Karen Morley (2008) – to name a few – have found ways to use this language of mythology, archetypes, and the gods to talk about leadership.

For those unfamiliar with Archetypal Psychology, the personages or gods represent aspects of the psyche and not actual figures living on Mount Olympus. They are (to borrow a phrase from Patricia Berry) condensed knots of meaning correlating with the way we imagine. The premise is that the mythology about the gods persists because it fits the way our minds work. Certain features or attributes cluster in such meaningful ways that they deserve being named. These gods are products of our imagination – an imagination we do not entirely control (see generally Hillman, 1975).

This article relies on the claim that the imagination is crucial to understanding leadership. Toward that end, it introduces two divine personages from ancient Greece, namely Hermes and Hestia. Their pairing signifies a psychological relationship of contrast and interdependence that leadership studies might consider in its investigations. For it is not my purpose to proselytize on behalf of pagan religion, but instead to exploit the mind’s capacity to populate its interior with vivid characters that reveal something about how humans imagine both the world and their places in it.

How did Hermes Appear?

The ancient Greeks recognized a god known as Hermes, whose identity was later found to be equivalent to the Roman god Mercury. Hermes had been a son of Zeus and therefore a half-brother to Apollo. He was ordained to the tasks of bearing messages on winged feet and of guiding souls toward their fulfillment at death. Although he tended to operate at night, he brought the unmistakable glow of divinity with him. Given his restless energy and his mission to journey from place to place, rather than dwell on Olympus, Hermes was thought to be the god of

travel. His image frequently adorned intersecting roads in Greece. Homer called him the "Wayfinder" (Kerényi, 1986, p. 16, citing the *Odyssey*, book V). Thus, he was both a herald of divine announcements and a leader or guide of souls.

Not coincidentally, Hermes' night of conception had been what the legend referred to as the fulfillment of the mind of Zeus, the achievement of a divine purpose (Kerényi, 1986, p. 20). This language – strange though it might seem to describe a sexual act – is important. In this sense of the fulfillment of the intentions of Zeus, Hermes became the mediator of divine purpose to an unsuspecting humankind that otherwise would wander abroad in the darkness. He finds wayward travelers and makes disclosures for the journey. Other texts choose to describe him as the one who allows humanity to "see through" things – a divine gift! (Kerényi, 1986, p. 26).

Unlike his half-brother, the remote and majestic Apollo, Hermes makes direct encounters with individual human beings. In these encounters, Hermes discloses something of the divine purpose, which it is his objective to accomplish by means of humans, creating a reality more attuned to the will of Zeus (Kerényi, 1986, pp. 51 & 54). As such, he governs a kind of in-between or middle realm: of a life underway and not yet brought to rest, of a project conceived and not yet finished, of non-being and being (Kerényi, 1986, p. 77). In these encounters, the illumination he brings causes an outpouring of the human soul to take initiative (Kerényi, 1986, p. 87).

In his infancy, Hermes had stolen the cattle of Apollo, and for that reason was known as a herdsman, the one who drives, escorts, and otherwise guides those who would otherwise not travel. This power of deft guidance, as Karl Kerényi put it (1986, p. 45), parallels the belief that Hermes herds the flitting, dead souls toward their final destination, in a different kind of darkness. Thus, Hermes was both an ambassador and a psychopomp (or one who delivers the dead), revealing purpose and then leading onward toward the realization of that purpose. As such, he occupies an intermediate position, neither remote and wild nor intimate and domesticated, but instead bridging two realms (Kerényi, 1986, p. 50, quoting Otto, 1954). Of course his willingness and ability to encroach on his mighty brother's territory shows him to be a master of stealthy border-crossings. Hermes is essentially liminal.

Kerényi concluded that Hermes represents an understanding that exceeds or transcends ordinary practical observation we well as scientific investigation. He never stays still. He says just enough. He renders intelligible that which had seemed opaque, but only enough to give direction in the moment, at this intersection (Kerényi, 1986, p. 55). By means of his statue, the erect penis pointing where next to turn, pious Greeks indicated his value to the lost (Kerényi, 1986, pp. 64f & 78).

If the metaphors of a dark night and being lost are not enough, Kerényi indicated that Hermes can be found in another place of obscurity, specifically in that "innermost nook" we call the human soul (1986, p. 83). There, his delightful incursion enthralls us in our "deep primordial darkness where one expects only animal muteness, wordless silence, or cries of pleasure or pain" (Kerényi, 1986, p. 88). The task of Hermes can be regarded therefore as "the conjuring of luminous life out of the dark abyss that each in his own way is" (Kerényi, 1986, p. 91).

Hermes is not without his liabilities. As a thief, he can be untrustworthy. As a messenger, he can delight in ambiguities. James Hillman viewed Hermes as the dominant archetypal figure in today's interconnected, global, instantaneous communication networks such as cable television, satellites links, and of course the internet, though his power has grown out of all proportion to his rank. People are becoming more addicted to information – rapid and jumbled information – than to meaning (2007, pp. 259-275). In a manner of speaking, Hermes also can be associated with abstract time, the relentless progression of uniform units, the minutes and seconds. This hastening world had become "intoxicated" with Hermes, looking to him for news when there is nothing in particular for him to report from the other gods. Instead, we feed his vanity and cry out for the latest update, the looping weather radar, the scroll across the bottom of the screen, so he gives us what he has: i.e. data. Abstract time and a plethora of scraps of information – inciting us to live desperately for the future, never content to let the truth unfold at its own pace, in the fullness of time (Hillman, 2007, p. 273). We now separate the image of receiving information from the divine message such information is supposed to convey (Hillman, 2007, p. 280). We have become greedy for facts and disdainful of wisdom.

All of which is to designate Hermes as a sympathetic messenger and guide for those who cannot otherwise find the way… swift and unpredictable, garrulous yet vague (Doty, 1980). He is a wayfinder, illuminating the darkness and pointing toward the numinous.

As it happens, the ancients understood that no god appears alone (Hillman, 2007, p. 278). The stories about restless Hermes in dark places were interwoven especially with another figure, the guardian of the hearth, Hestia. Their pairing suggests a kind of counterweight or complementarity, at opposite ends of a spectrum, in some respects, yet part of the same whole. Let us turn to Hestia next.

How did Hestia Appear?

Just as Hermes races against time to appear in many places and facilitate adventure, Hestia was assigned to one spot (Hillman, 2007, p. 237, quoting Paris, 2005). In fact, her place was at the epicenter of human habitation, "a symbol of permanence, of fixity, of immutability, of centrality…" (Goux, 1983, p. 92). Hermes flew just above the surface of the earth; Hestia's power is entirely earthbound (Goux, 1984, p. 92). If Hermes suggests urgency and future-oriented striving, Hestia represents "endurance" and "perpetuity" and "continuity" (Goux, 1983, p. 92f). If Hermes lapsed into abstraction and ambiguity, Hestia was affixed to a very specific place and kept a stolid vigil over the home fires – simple and concrete (Hillman, 2007, p. 238, quoting Paris, 2005). Whereas Hermes delivered light to darkened and wayward humanity, Hestia tended the light at the hearth. She embodies in her image the preposition "in" – interiors, indoors, insight, within enclosed spaces (Hillman, 2007, 230-241). She represents the "idea that what is most sacred…is inside" (Goux, 1983, p. 98).

Hermes without Hestia becomes free-ranging, spastic, happy to scurry about delivering pointless messages that have no other sanction, jerking his victims this way and that, living in anticipatory anxiety. He becomes, like humanity, a vagrant (Goux, 1983, p. 97). Hestia, on the other hand, keeps things at home tidy, grounded – in a word, focused, by which we mean "disciplined attention" (Hillman, 2007, pp. 235 & 269; Kirksey, 1980). There is a stillness there

… inside. While Hermes transgresses from the beginning, Hestia's very name derives from the Indo-European "to abide" or "to inhabit" (Hillman, 2007, p. 235) – to stay or stand within the boundaries and preserve an atmosphere of welcome. In a word, Hestia counterbalances or brings to dignity the mercurial Hermes.

It is instructive, I think, that as a goddess Hestia was tended more by political leaders than by religious leaders. Political leaders had a stake in preserving the polis, seeing to its perpetuation, the practical affairs of executive office (Kajava, 2004, p. 5). There was even a public hearth and not just the private hearths at home, and it was the duty of these civic leaders to maintain it – in homage to Hestia (Goux, 1983, p. 92). Plato and Aristotle advised that judges subject themselves to the presence of Hestia before they render a decision (Goux, 1983, p. 99).

And though we are all familiar with the idea that Hermes delivers tidings, Ovid exclaimed that it was in contemplation of Hestia that "my ignorance was enlightened and my errors corrected without the help of an instructor" (Goux, 1983, p. 93, quoting Ovid's *The Fasti*). The point is that she does not deliver a message. Her mere presence is enough. She even convinces the poet not to depict her in any way, which is consistent with her unique status as the divinity both Greeks and Romans were reluctant to portray in their art (Goux, 1983). She conveys no image. Presence has to be enough because she is not to be approached; she is inviolable (Goux, 1983, p. 95). She is forever – by choice and by decree – a virgin.

Barbara Kirksey speculates that it is by means of Hestia that we can imagine, which means that she is the light by which we see and not the object of our seeing; she is not unlike the spotlight for a stage. The audience does not turn and look at the light bulbs (1980, p. 109).

Eventually, the myth leads to confusion if our purpose is to detect direct analogies. Is Hestia the essence of the sacred that is not to be touched, or the virginal composure of the soul as it awaits the impress of God? (Goux, 1983, p. 97f). In either case, wrote Cicero, Hestia is the custodian of innermost things, where these profound encounters take place (Goux, 1983, p. 98, quoting *De Natura Deorum*).

Kirksey offered several useful lessons on Hestia that are relevant to our purpose. If Hermes is the wayfinder by the side of the road, Hestia is the center, both home and hearth. By being so "inward" we would say that she is intimate, connected, at the place where the psyche encounters the cosmos – like the omphalos, a scar where we were attached (1980, p. 111).

Hestia represents a gathering place or focus. But then, she remarked, focus requires adjustment, a kind of subtle shifting of the lens to bring convergence, which in photography we might call the "sharpness" of the image (1980, p. 111). It is we who must adjust, adapt, fiddling with the mechanism by which we see – or "bringing" it into focus. In this sense, Hestia not only illuminates and makes manifest, but also governs the delicate fine-tuning we must undergo to remain connected.

Why would it have been helpful to become acquainted with Hermes and Hestia?

Perhaps the most obvious reason to consult mythology is that it shows the continuity of symbols over time. There were primordial analogues to philosophy, science, and the arts. Retaining this continuity, in one form or another, tends to strengthen the insights of an investigator, because if he or she had completely invented a new story, without any continuity at all to the prevailing culture, then the community would have been resistant to that message. The existing symbolizations make communication easier. A Sigmund Freud can find references to the story of Oedipus helpful in explaining his hypothesis. In this way, the myths connect us to tradition by offering a language which the people already understand.

More than that, there is bound to be a convergence of symbols around the self-same experiences. (This is the contention of a Joseph Campbell who can find parallel stories in multifarious and far-flung cultures, from which he infers a commonality of experience. Similar stories, similar experiences). If you and I have an equivalent experience, it is likely that our descriptions will in some respect resemble each other. Myths are early attempts to explain something that we still need to understand, and it is possible that we can still learn something from these time-tested narratives.

Plato for example was not exactly replacing one thought system (Homeric gods) with another and consciously overthrowing an entire tradition. He was differentiating something that had previously been compact. This is why he had to take something that already existed in the culture and reveal these differentiations as an advance on our understanding. Two thousand years later many of antiquity's differentiations have not been improved since; if anything, they have been corrupted in the West, often grossly oversimplifying a complex reality. The myths offer us a compactness that in many cases we have otherwise lost.

Archetypal psychologists will argue that the myths survived because they reflect or enact dynamics in the soul. There will be a kind of validity to a story that captures what happens in each of us. We can "relate" to the tale, and that is why it survives. These archaic images are the archetypes that shape human thought. Thus, whatever it is that we hope to understand will originate in a common reservoir of images derived from the polytheistic worldview of the ancients. "To study human nature at its most basic level," wrote James Hillman, "one must turn to culture (mythology, religion, art, architecture, epic, drama, ritual) where these patterns are portrayed" (Hillman, 2004, p. 14). He continued, "The primary rhetoric of archetypal psychology is myth" (2004, p. 31). And the fundamental component of mythology for purposes of understanding the human soul are its images (Hillman, 2004, p. 26). When these timeless images are encountered, they frequently arrive as personifications bearing a message (Hillman, 2004, p. 25).[2] That is how we often understand them. Thus, we give them a name. And so we find ourselves encountering Hermes and Hestia.

---

[2] Hillman explicitly distinguishes a polytheistic account of the soul from a polytheistic religion (2004, pp. 45-49). It was not his purpose to demonstrate whether the cosmos is actually populated by divine beings bearing the likeness of Zeus, Apollo, and Athena.

One final observation about the relevance of Hermes in particular to our investigations into leadership. It is from the name "Hermes" that scholars adopted the term "hermeneutics" to mean interpretation – originally, the interpretation of sacred texts. They wanted to formalize their efforts to interpret texts that were notoriously difficult to understand. These texts were often partial and cryptic, recorded in an alien language, during a remote era, as part of a foreign cultus, such that interpretation was required to make sense of them. The goal was to adopt standards for conducting these interpretations. Out of the evolution of these standards a name for this effort emerged based on the Greek god Hermes, by way of *herméneia* for the English word "explanation" (Kerényi, 1986, p. 88).

In like manner, leadership studies has been one long, sustained effort to interpret something that is not always directly accessible to observation, a looking past what is apparent to something behind it, into the interior of social actors – their fears and desires, their hopes and dreams. And to do this, of course, we have to interpret the scholarship of many writers – the scientists, philosophers, and historians who have tried to make sense of leadership, but also the dreamers and artists. Interpretation has been the name of this collaboration. You and I and leadership scholars (as observers) and leaders and followers (as participants) all engage in processes of interpretation en route to making choices about what to do in the world. It seems useful to say this openly and make it plain. Thus, we might say that Hermes represents the activity of particular interest to us.

Hermes and Hestia, Together

One could argue that – to one degree or another – each of us embodies the gods. We pass through phases or episodes in which they possess us: anger for Aries, love for Aphrodite.

Hermes is a kind of leader, attracting attention from those in liminal spaces, uncertain where to turn, and pointing the way toward fulfillment. He even accompanies us, supplying hints and intimations as we go on the path we are meant to follow. He brings the boon of direction. His illumination draws our attention in the darkness and lights our footsteps.

Hestia awaits us, keeping the home fires burning, tending the point of convergence, where we all are meant to gather and abide together. She is the steady attraction, a fixed point we must use to orient ourselves, lest our lives become unfocused. If Hermes lapses occasionally into exasperating, manic abstraction, whirling about on winged sandals, getting carried away by rumor and speculation, she is the most concrete thing there is … a touch, a warmth, a place to eat and rest. And so they work together, animating our choices about when to follow and whom to follow – the lively, gesticulating, charismatic Hermes, enlivening the imagination to venture forth, toward the feminine embrace of fulfillment at the place where we somehow know that we belong.

Stella Adler: You Have NO Expertise on Costume

Al Erdynast[1]

Opportunities for exchanges with persons of exceptionally high degrees of expertise and operating principles in their field are rare. This article is a study of Stella Adler. Unbeknownst to me when we first met, since we were in different fields, Stella Adler was the queen of acting teachers in the theater and movie industry, with whom Marlon Brando, Robert De Niro, Cybill Shepherd, Benicio del Toro, James Coburn and so many other legendary actors had studied. The American philosopher John Dewey discusses various types of experiences in his book *Experience and Education*. Most of our experiences are benign – not constructive, not destructive and such experiences are transitory and often not remembered. A few rare experiences are formative and lasting – they deepen our future experiencing. The most transformative type of experience is the formative kind that lives on fruitfully in future experiencing. Stella Adler lives on in some of my analyses of Picasso's works, thirty-five years after her own analysis of Picasso's Bull Series. Thirty-five years! Precious few experiences have that kind of longevity.

I met Stella Adler in 1982 in Los Angeles through Milton Justice who was working on Lee Grant's documentary for HBO entitled "When Women Kill." Lee Grant had selected six women convicted of murder, three of whom were in New York, and three likewise convicted in California. At the time I was teaching a class in a women's prison. That class was one of eight classes I taught each year, two of which were at the prison. The class was part of a special B.A. program for incarcerated women, and was based on a study that found that the rate of recidivism was considerably reduced when inmates completed at least 3 college courses. An inmate in my prison class, referred to as one of the Manson Girls, was one of the women selected by Lee Grant. Milton and I met to prepare for the filming of my prison class. During our discussions, Milton frequently quoted Stella. The quotes were highly interesting positions she took on a wide range of issues.

Milton asked if I would be interested in attending one of Stella's class sessions while she was in Los Angeles. I was intrigued, so I answered, "Yes, I would." The classroom was in an amphitheater. Milton and I sat in one of the upper rows in the back. Stella was seated at a desk with her assistant. The students had each prepared a 15 minute scene. Invariably, Stella stopped each performance within a minute or less, critiquing what the students were doing and giving them instruction. Her critiques were impressive and exceptionally astute. She was a master at her

work. Some of her criticisms were unnecessarily harsh. A few acting students thought the criticisms were personal attacks and sometimes cruel.

I was not previously familiar with who Stella Adler was. I did not know that she had been an actress and a director in the Group Theater. I did not know she was a legendary acting teacher and that she also infused social criticism and humor into her classes. I did not know she had had numerous adventures throughout her life. Nor did I know anything about her unique persona, her immediacy and that she could be a force of immense proportions.

When class ended, Milton introduced me to Stella and I offered my compliments. Stella invited us for a late supper along with other former students. After some chit-chat from her former acting students about how well she had taught the class, Stella turned to me and asked, “And what do you do, young man?”

Before I could answer, Milton, who had previously been one of Stella’s assistants, introduced me, rather theatrically, as a professor who teaches women who’ve been convicted of murder.

His answer was an exaggeration. Most of the inmates in my class had convictions for other crimes.

What happened next was striking. Stella turned to the person beside her, directly addressing the central issue about the topic that was brought up, which was very characteristic of her, and asked, “Could *you* ever kill?” Then she asked each of the other 10 guests the same question. Her forthrightness was not something to which I was accustomed. It was exhilarating. One dinner guest said, “If it hadn’t merely been a shoe that I had thrown at my former husband’s head, he’d be dead.” The two individuals who declared they could never kill, under any circumstance, were perhaps the two most dangerous people in the room. Not even in self-defense? Not to protect the life of an innocent child from a homicidal maniac?

The next morning I received a phone call from Stella’s current assistant, Eddie Weinbaum, who said, “Miss Adler would like to invite you to join her at a party she is having this weekend for distinguished actors, directors, and producers.” I was surprised and flattered. The invitations continued. I am a relatively busy person, someone who hadn’t the time to attend many social events. But time is made, not found, to be with Stella Adler. Every day when the call to my office came with an invitation, I made the time to join her. I was Stella’s companion at dinners, parties, and other social events. She was 82, but she lied about her age. She told me that she was 81. I was 38.

Once, Stella gave a dinner in honor of the writer Christopher Isherwood. As the guest of honor, he was seated to her right. For the first time since I was introduced to her a month earlier, I was seated to Stella’s left. Among the guests at the dinner were Isherwood’s partner, portrait artist Don Bachardy, and Dr. Ann Reynolds, who was the Chancellor of the California State University. Dr. Reynolds, who governed the University through 19 campus Presidents, had invited Stella to visit Russia with her for a tour she planned to make of universities there. Stella, who was born in Odessa, was tickled by the invitation, but was undecided about whether or not to go on the tour.

An hour of cocktails preceded the dinner. One of the guests arrived late and tried to give an explanation for his tardiness. Stella interrupted him, “Explaining why you are late because of traffic in Los Angeles is not worthy of adult conversation.”

Fifteen minutes into the dinner Stella turned to me in a loud enough voice so that all could easily hear, “After these dinner events, Al, do you go home to your wife?”

The entire dinner table immediately lost interest in whatever it was they’d been chatting about.

I answered, “No, Stella, I am not married.” She paused for a few seconds.

Stella then asked, “Al, after these evening parties and dinners, do you go home to your girlfriend?”

“No, Stella, I don’t have a girlfriend at this time.” Stella pondered her next question while everyone else was very quiet.

“Well Al, then what do you do for sex?”

I had never previously been asked that question at a formal dinner. I have never previously been asked that question at an informal dinner either. But I had already learned enough about Stella Adler to know that questions of this sort can arrive at any time, whether expected or not. Her forthrightness was on par with the question, “Could you ever kill?” No question that Stella ever asked was one that could be avoided.

“In those matters,” I answered, “I am of the same persuasion as the two philosophers Immanuel Kant and Mae West: “Work is the ultimate satisfaction and sex is the ultimate distraction.”

Stella banged her fist into her other hand and said, “I am the very same way! On my bed in New York, instead of a man, I have fifty books.”

It took me some time to realize that Stella was not really inquiring about my sex life. She was simply probing my availability.

Stella’s marriage to Harold Clurman – director and producer in the Group Theater – had considerable turmoil, in no small part because Stella accepted dinner invitations from other men. Her mother-in-law pulled her aside one evening to educate her about proper marital etiquette. “Stella, when married you are not supposed to date.” Stella said, “Really?” But she continued to date.

At the end of her summer of classes in Los Angeles, Stella invited me to join her on vacation in Italy and France, where she planned to visit art museums. I told her I was extremely flattered, but that I couldn’t go – I had a university to run. These days, no longer an academic administrator, I am simply the senior member of the petrified faculty at my university.

A week later, after reconsidering her plans, Stella presented a different proposal – if she cancelled her trip to Europe, and if she postponed her nightly early dinner invitations with directors, producers and actors in favor of later suppers, would I tutor her for three hours every evening, from 5 until 8 p.m., on various areas of my studies? I very gladly accepted.

So for the next three weeks I tutored Stella in some of the areas in which I taught, using mostly my course materials on Mark Twain, Picasso, and the Psychology of Adult Moral Development. Stella came to admire Mark Twain as a social critic and as an educator, which is how he understood himself rather than as a humorist. She was particularly impressed with his scathing critique of the Belgian King Leopold II for his colonial policies in the Congo. She was delighted with Mark Twain's description of his meeting with George Bernard Shaw, who was one of Stella's favorite playwrights and social critics. Stella had her own gift and courage of spontaneous humor, but she had not studied humor nor cultivated it into a discipline. She admired and respected power through writing, but she had never previously imagined that Mark Twain's form and style of philosophical humor incorporates enormous power—"Under the assault of humor, nothing can stand."

We didn't cover my course, Moral Psychology in the Dramatic Film, since it paralleled her course on script analysis. My class analyzed *Casablanca*, *The Philadelphia Story*, and *Betrayal.* We both taught about Edward Albee's works. In Stella's classes she covered his plays *The Zoo Story* and *The Death of Bessie Smith*. In my film course I analyzed Albee's *Who's Afraid of Virginia Wolf?* Because of the overlap of our two courses, Stella once asked me to be her teaching assistant to prepare teaching notes for George Bernard Shaw's *Major Barbara*. Not uttering a word was a novel experience for me as a professor as I sat with her during the class session. I later received a letter from Stella, letter writing for which she was also famous, expressing her appreciation for succinctly condensing *Major Barbara* for instructional purposes. She also humorously expressed her gratitude that she did not have to suffer George Bernard Shaw's excessive wordiness that evening.

How clever of Stella to get a professor to be her teaching assistant. Why didn't I previously think of that for myself? But I am a quick study. The last time I submitted a several hundred thousand dollar research grant proposal to the Templeton Foundation, I asked the President of my university to please review the proposal before signing off for our university. The President found a typo. Presidents, with a Ph.D. degree, are good at this. Actually they are the best. No one can surpass the presidents of universities in locating typos in research grant proposals. And they are deservedly proud and happy when they locate a typo, and have it corrected before the proposal's submission.

Stella overcame her objection to what she had previously, and mistakenly, referred to as Picasso's "abstract art." She understood Picasso as a vehicle for better understanding the aesthetic universe. In a parallel way, Stella taught script analysis as a vehicle for understanding the human condition. We discussed Picasso's Pink Period paintings, particularly *Woman Ironing (1904)* for its depiction of the state of resignation. We discussed *The Blind Man's Meal* (1903) and several other Blue Period paintings as well. We analyzed Picasso's *Weeping Woman* (1937) for its depiction of the intensity of distress and unavailing grief. The emotional issues in these Picasso paintings were ones addressed by the playwrights about whom she taught.

Stella Adler, who was the master teacher to many prominent actors, suddenly was my student. She was obviously the brightest student I have ever taught.

Stella invited me to visit her in New York, to her apartment on the Upper East Side, and also to her house in Southampton, where she said I would have my own room to do my research writing. During my visit to New York City, she invited Lee Grant and Michael Moriarty to a dinner party, along with other guests as well. After the dinner, Michael asked Stella's permission to rehearse a scene from the *Caine Mutiny* – in which he had the starring role on Broadway – for her opinion and critique of his interpretation. It was impressive to listen to Stella's astute, critical review of his performance and to listen to her generous opinions about how Moriarty could improve his interpretation. I was enthralled by his honest and sincere request and by Stella's thought provoking response.

After Stella and Michael had completed their work, while everyone was chatting, Stella boomed, "Well, Al, everyone in New York wants to know, do we or don't we sleep in the same bedroom? What should I say?"

"I hope you have answered, 'Yes,'" I said, "because I don't know any instance in history that saying 'No' makes any difference in what people think." Stella and the others smiled.

Once, on our way to Southampton, Stella instructed me to turn right at a fork in a particular intersection. I turned left instead. Stella said others would have turned right because they loved her. I replied that her acting students, whom she employed to chauffeur her, would have turned right not because they loved her, but because she refused to acknowledge that slavery was against the law. She grinned. I then informed Stella that a road sign at that particular intersection had instructed drivers to turn left to get to Southampton.

Back in Los Angeles, Stella and I once attended *"*Zorba the Greek, the Musical" with Anthony Quinn, one of her former students, starring in the lead role. We were seated in the house seats – ones that Anthony Quinn had personally provided at the Dorothy Chandler Pavilion. Shortly after the performance began, Stella suddenly wanted to walk out. Stella had undoubtedly been influenced by her father Jacob Adler, king of Yiddish theater, who lived by the principle that the playwright, and the director, decide on the moral content of what was presented. Her father told audiences that if he did what *he* thought he should do *they* would then learn about Yiddish theater, but if he did what the *audience* wanted him to do, it would lead them both straight to the whorehouse. So that night, while watching *Zorba the Greek,* Stella saw that Anthony Quinn was pandering to the audience's desires. And she wanted no part of it. Stella stood up in her seat to exit, but I told her that we could not leave the theater just yet. She said, "Of course." She understood that the issue was one of public decorum. The spectacle of Stella Adler leaving her front-center seat before an audience of several thousand would have been scandalous. She and I suffered more of the musical, but only until the intermission. Then we emancipated ourselves.

Stella, who had once been on the teaching faculty at Yale University and the New School for Social Research wanted to meet my former mentor, Professor Lawrence Kohlberg, with whom I studied while at Harvard University. I said it was not a good time to meet him, that he was terribly depressed. Stella immediately wanted to know why he was depressed. I said, “He is the world’s leading expert on moral development, his books have just come out, and the critics have been harsh.” “That's normal,” said Stella. “What else?”

“He is in the middle of a bitter divorce and says his wife is suing him into poverty.” “That’s normal,” said Stella, “What else?”

“He is not on speaking terms with either of his sons.” “That’s also normal,” said Stella. We never managed to make the trip so she could meet my professor.

Stella and I visited the Norton Simon Museum in Pasadena one day. Stella wanted to only view the French and Italian painting exhibits. As we entered the museum, however, I fortuitously happened to spot Picasso’s Bull Series. I asked if she would mind giving me her opinion about whether the series of bulls was beautiful or not, since I teach about that sequence. She said, “Yes, I *would* mind.” Her analysis of Picasso’s Bull Series was superb, despite her protestation that she had no interest in “abstract art.” I found her analysis more interesting than either of the only two published analyses, one of which is by a former Curator of the National Gallery of Art in Washington, D. C. I told her that Picasso denied he ever painted any abstract art, declaring that everything he painted came from reality. Stella’s analysis of the Picasso Bull Series had an influence on my own analysis, and more recently, 35 years later, on a research study that involves the analysis of Picasso’s *Les Demoiselles d’ Avignon*.

I invited Stella to my class in prison once so that she could present her analysis of the Bull Series. Stella told the inmates that Professor Erdynast had “forced” her to analyze the Picasso lithographs with the question, “What do you think?” A question that, according to Stella, “no self-respecting intellectual can ever avoid!”

Stella told the inmates that her expertise in the discipline of script analysis was related to the discipline of art analysis. She also told them that twice she’d come close to finding herself at risk of being sent to prison. During World War II, Stella illegally tried to take displaced persons on a train to freedom described in detail in Sheana Ochoa’s excellent book “Stella!!!” She was also a member and a gun-runner for the Irgun, a militant Jewish underground organization in Israel. Stella told the inmates that one of the Irgun’s leaders was Menachem Begin, a friend of hers who eventually became the Prime Minister of Israel. Stella additionally talked about having once been caught arriving in London with two different passports.

Stella made an indelible impression on the inmates and the “free-world” Antioch University Los Angeles students who had come to the prison for the day. Making an indelible impression was a common feat for Stella in all settings. Stella was an intellectual magnet who attracted the interest of exceptionally talented and highly motivated actors as well as that of beginning acting students. She was a true genius. And true genius does not limit itself exclusively to a single field; it manifests and extends itself pervasively.

One of the inmates in the class, who was featured in Lee Grant’s documentary, made a particularly good impression on Stella. Stella said she would like to take her shopping one weekend. I had to educate Stella that an indeterminate life sentence does not come with weekend shopping privileges.

Stella’s third husband, Mitchel Wilson, was the most popular Western scientific writer and novelist in the Soviet Union. He had been a research scientist assisting Enrico Fermi and had taught physics in universities. Science, invention, and the ethical problems of modern atomic physics were topics he routinely addressed. One day, while he was reading a book in their living room, Stella came up behind him, looked over his shoulder as he was reading and asked, “That looks terribly complicated. Can you understand all of those formulas?” Mitchell answered, “Yes, Stella. I wrote this book.” She once told me to stop playing tennis, that it was unbecoming for an intellectual to be chasing a tennis ball.

On one occasion we had cocktails with Harold Williams who was the president and chief executive officer of the J. Paul Getty Museum and the Getty Trust. During the conversation Harold Williams said that the Trust had let it be known in art circles that it had so much money it could offer $1 more than any other bidder, outbidding any and all rivals. Stella boomed out at him, “There is no museum art for sale.” Several years ago, Italy sued the Getty Museum to return its illegally procured art. In my course on Picasso, I take students on several field trips – to the Norton Simon Museum, the Los Angeles County Museum of Art, and the Weitzman Museum in Holmby Hills. I announce to the students that I could also take them to the Getty Museum, but won’t, to show them where some Italian art used to hang.

In Palm Springs one weekend, one of her former students, Misty Rowe, came to visit. Misty had a lead role in the television series *Hee-Haw*. After dinner, Stella wanted to go into the swimming pool, but she didn’t have a personal assistant along to help her get into a bathing suit. She asked if it was ok with me if she went skinny dipping. I said, “Of course.” And the three of us went for a swim. Had I not been so agreeable, I could easily have come into criticism for having what Stella referred to as “middle-class Puritan attitudes and values.”

It was almost always Stella who invited me to her social events. Occasionally, I invited her to one of mine. As the Director of the B.A. Program at Antioch University Los Angeles, I once had to give a short graduation speech at the California Institution for Women, the state prison where Antioch’s Bachelor of Arts for inmates was being provided. I invited Stella.

It was a delicate speech to deliver. Most of the women in the program were there for a single – but major – crime in their life. They were ashamed that their paths had taken them to prison. The inmates’ families were present as the graduating women received their diplomas. The parents and husbands were ashamed that their daughters, or wives, were in prison. The inmates’ young children were bewildered by their mothers’ circumstances. My short speech addressed the inmates’ achievement in pursuing their formal education while they were “doing time” and not “letting time do them.” Shame was temporarily suspended and substituted with pride of accomplishment.

On the drive back from the prison, Stella, who was renowned for her course on script analysis, retraced the sequence of points I’d made in my speech. I should have expected it. We talked about the particular influence of violent, imperious men in the lives of the inmates that had led some of those women to prison sentences. Some were serving 15 to 25 years. Some were there for indeterminate life sentences.

Stella had worn a black blouse and a black corset underneath to the prison graduation event. At this time in her life, at least while in Los Angeles, she usually wore only a thick black or red ankle-length slip that her personal assistant, Eddie, had thoughtfully arranged to be made for her at *Trashy Lingerie*. The slips, which she wore as dresses for teaching her classes, were comfortable, convenient, and eminently practical. After a hip replacement surgery Stella no longer had her previous physical flexibility. With those thick slips, worn with a jacket, she didn't have to put on a cumbersome bra underneath. A couple of times I teased that I would publically let it be known that her entire wardrobe had been obtained not at *Saks*, but at *Trashy Lingerie*. The preposterousness of the possibility, and her confidence that I would never execute that threat, made Stella grin with abandon.

It was an extremely hot day at the prison on the day of the graduation and there was no air conditioning. I don't ever complain about excess heat. I could in fact be called "an optimist who hasn't quite arrived." I look on the positive side of things. I think of excessive heat as preparatory for my eventual destiny. Stella didn't complain about the heat either. But on the long ride home she was visibly uncomfortable in her ensemble and asked if it was okay if she could make herself more comfortable by unbuttoning her blouse. I said, "Of course." I was not bothered at all. Had I objected I could again easily have come into criticism for "middle-class Puritan values and attitudes."

When we arrived back in L.A. after the long drive, I offered to take Stella out for coffee at the *Farmers Market*. She said she would like that very much. But Stella's blouse was still unbuttoned—all the way. I asked if she would mind re-buttoning her blouse. I thought of it merely as a matter of public decorum. The moment I made that request I immediately knew there was going to be trouble. Stella was rarely at a loss for words. Her temporary silence confirmed that trouble was being prepared. The queen of acting teachers, with whom so many legendary actors had studied, only *gave* instructions. The queen of acting teachers *took* instructions from no one. Throughout her personal history, in any situation with rival interests, Stella almost always prevailed. And she could be fierce when necessary. Stella answered that she "would *indeed* mind" re-buttoning her blouse.

I had to decide whether she was serious or not serious. Stella had previously forewarned me with, "Always remember, Al, that I am an 'actrissa' (her affected aggrandization of the word 'actress') and that an actrissa is *always* acting except when she is on the stage." After brooding for a bit, she complained that the previous week I had voiced no similar objections when we had gone to the fashionable restaurant *The Ivy* with Misty Rowe, where Misty Rowe wore a camisole top. She then thundered: "You have NO expertise on costume!"

Her indictment was compelling and dispositive. Not previously, nor since, have I been told in such a straight-forward, dignified and civilized way, in the heat of intense anger, and without character attack, to mind my own business. Not only was I no professor on costume, in my entire life I had never impressed anyone serious about style in dress in any way that would even qualify me as being a worthy student in that field.

Stella was undressed in only a most minor way. It was I who was exposed – I had been caught with my credentials down. I had taken a position on an issue with no expertise on it whatsoever. Mine was the conventional point of view. Stella challenged my request, in a realm where she had considerable authority and I had none at all.

The defense had no rebuttal.

The impasse in the parking lot was a private spectacle – the queen of acting teachers who objected to a simple request and a professor at a loss for words. For a considerable length of time Stella and I continued to sit in silence in the parked car. I had been rendered completely and utterly speechless – a fine predicament for a professor who taught courses in five different disciplines, with not a helpful word arriving from any of them. Stella was reverberating from the infernal presumptuousness of a blandly attired professor, wearing an innocuous button-down shirt and tie, a sport coat, and grey slacks, who had given her – Stella Adler – an instruction on dress!

The tension had to do with decisions about matters of attire. Unbeknown to me, Stella had intense views about professional and public attire. The A&E documentary on Stella Adler, which is part of its *American Masters* series, illustrates this intensity. Stella is visibly enraged by a young student who dressed for his own comfort when he performs a scene from Shakespeare. Stella interrupts him and criticizes him severely, telling him that wearing a casual robe is incongruous with Shakespearian period costume. And she states that she refuses to be subjected to self-indulgence, which she abhors. She mentors him – affirming his considerable talent but adds that if he doesn't select his wardrobe to suit whatever role he is portraying that he will professionally undermine himself.

The young student whom she berates in the documentary is Mark Ruffalo.

Stella swore she would make me pay for my insistence about re-buttoning her blouse. When we eventually came out of the car, Stella was fully buttoned, and behaved in a manner fitting a famous acting teacher, greeting all those who recognized her and rushed to meet her. But they would have greeted her equally well if she had been unbuttoned because she had considerable poise, presence and carriage no matter how she was dressed. Stella was born to parents who were royalty in the Yiddish Theater and, in her adulthood, she certainly became an intellectual aristocrat in her own right.

No experience with Stella was ever benign. Experiences with Stella Adler always resulted in more profound experiencing.

It was her graciousness that prevailed. She never did carry out that threat.

Of course!

Subject Object Poem

Imagine a world with no mirror,
no camera, nor lake without haze.
How would I know what I look like?
Where would I look for my face?

Would I be fair like the maid in the story?
Or hideous, a walking disgrace?
I could try and feel with my fingers,
or I could tell from the look on your face.

But all that I meet, they are different.
Some adore me, some run in detest.
Some want me to tell them what I see,
some say that not knowing is best.

Now, picture me finding a mirror.
At last I can see who I am!
I see tears rolling down on my cheeks as I
admire the face I will damn.

Now I'm travelling the world with the truth in my hand
showing everyone who they really, truly are.
Soon I'm hated, haunted and crying,
but not from loneliness, isn't that bizarre?!

No, I'm crying because I just realized,
that the face in the mirror I see
is yet another part of my body.
If I see it I know it's not me.

Orange Capitalism – and then what?
A review of two books on the future of economy and society

Dawlabani, Said. (2013). *Memenomics – the next generation economic system*. NY: SelectBooks, Inc.
and
Scharmer, Otto and Kaufer, Katrin. (2013). *Leading from the Emerging Future: From Ego-System to Eco-System Economies.* San Francisco: Berrett-Koehler Publishers, Inc.

Reviewed by Kristian Stålne[1]

What caused the 2008 financial meltdown and where is capitalism heading after that? Or maybe we should rather ask where we as global society as a whole are heading, since economy is such a fundamental part of our lives and societies. This complex topic has been widely discussed with many analyses and speculations on the nature and development of economy and money. But what would economic development look like through an integral or developmental lens? I have found two such analyses of interest that seem to qualify and that are mostly compliant yet complementary with each other, but still very different in style and focus.

The first one is *Memenomics – the next generation economic system*, by Said Dawlabani (2013) who employs Clare Graves' double helix or Spiral Dynamics model as a developmental framework (Beck and Cowan, 2006), and the second one is *Leading from the Emerging Future: From Ego-System to Eco-System Economies* by Otto Scharmer and Katrin Kaufer (2013) that introduces an own developmental framework for socio-economic development. One of my research foci is on stage theories in adult development psychology that typically takes the individual, and to some degree the culture, as a study object, but I also have an interest in connecting adult development and integral perspectives with sustainability and societal development. Therefore my main interest in these books is whether and how they make this connection. Do they give a view on the stages on socio-economic development that are consistent with each other? How do they view the current and prevalent structures and state of affairs? Is there a problem and if so, what comes next and how do we make the transition?

I will start by giving an overview on Dawlabani's analysis on the economic development and view on the financial crisis, and then compare and contrast with Sharmer's and Kaufer's perspective on the same. As said, my main focus is on the developmental frameworks they employ and how these can help us understand the grand challenges we are facing and some of the limitations of the current capitalist economic system. With help mainly from the second book I will map out some of these challenges and proposed ways of addressing them. Sustainability is of central concern in these and I will also relate the proposed developmental frameworks with other frameworks used in mainstream discussions along with some own suggestions for further studies on this vast topic. Finally, I will refer to a brief description of what a Turquoise economy would look like, according to Spiral Dynamics and Dawlabani.

Memenomics – Spiral Dynamics Applied to Economic Development

Dawlabani's book takes the Spiral Dynamics model as a framework for analysing the economic system. Spiral Dynamics maps out eight value systems or vMemes, where each of them has as its purpose to solve the problems of existence that it perceives. By doing so it creates a new set of problems that will trigger the emergence of and will be addressed by the next value system. The rise and fall of each value system is described in terms of six phases: Inquiry, Introduction, Growth, Maturity, Decline and Entropy, although the vMeme will still be present as the next higher stage emerges. The values systems, or vMemes, are commonly referred to by colors and here very briefly introduce along with approximate time when they first emerged in human history (Beck and Cowan, 2006):

Beige (100 000 BC), focusing on physiological survival needs in the dawn of humanity;
Purple (50 000 BC), associates with magical thinking in hunter gatherer tribes;
Red (7000 BC), affirming own needs and will to exploite and dominate others;
Blue (3000 BC), traditionalistic absolutism and self-sacrificing obedience;
Orange (1000 AD), modernistic and industrial with rationality and scientific objectivity;
Green (1850 AD), postmodern with pluralism, multiculturalism and human connection;
Yellow (1950 AD), a functional integration of the previous levels' healthy aspects;
Turquoise (1970 AD), identifies with the world as a holistic organism.

According to the Spiral Dynamics lens, the economic system can be seen as a consequence of our worldviews and our value systems, which in turn is a function of *life conditions*, and vice versa. Thus, the way the economy functions is a fundamental part of how we organize our societies. Another characteristic is that one level transcends and includes the previous one and that levels cannot be skipped, or rather *should not* be. This means that one should not try to impose a more complex economic system, or governance, on a culture than what is consistent with the life conditions and vMeme distribution of that culture.

The book focuses on the economic aspects of cultural development up to today's capitalism and market liberalism, followed by a detailed description of the development of the US economy leading up to the financial meltdown of 2008 and finally a discussion on a solution and next step economic system referred to as *functional capitalism*.

The first part gives the economic historic background according to the Spiral dynamics, beyond the first Beige value system or vMeme:

Purple – the gift economy of the hunter gatherers

The earliest form of economic activity took place in the form of bartering or gifting, which was an important if not necessary means of creating a peaceful existence between different tribes instead of pillaging and waging war against each other. The goods that were traded were food (from hunting and gathering as well as grain from early agriculture), artifacts, jewelry and precious metals.

Red – the first civilizations and the emperor's coin

As civilizations were born and grew to be complex and stratified, organized economic systems were created that allowed for exchange of goods and labor within the empire. The emperor would create money in the form of coins made of gold or another metal accompanied by laws to force the subjects to accept them as means of payment. We could refer to this as concrete money since they had an inherent value in the metal itself.

Blue – nation states and national banks

Along with the birth of nation states, national banks and industrialization, the use of banknotes or paper money backed by gold became wide spread (although banknotes first were used in periods in China already one millennium before). Despite some initial bank runs, when people lose their confidence in the banknotes and want to trade it back for gold, this new and more complex abstract form of money was established in society (the complexity aspect is not discussed in Dawlabani's analysis). With a stable currency that everyone trusted the new industrialized economy could flourish. Hallmarks of the Blue value system are trust, order, justice and stability, which are required preconditions for a functioning economy where you exchange goods, wages, and you can borrow and repay money, which paved the way for capitalism. This economic system was a huge step forward for society, but still one that showed several limitations, e.g. that the wealth of a state was dependent on the size of its gold reserve.

Orange – market economy and capitalism

Gradually the western mindsets and economies shifted towards an Orange mode of thinking, meaning more individualistic, with less centrally controlled and regulated economies, and positivistic towards scientific and technological progress, and towards economic growth. In the USA in 1971 the currency was shifted away from the Bretton-Woods framework, thus releasing the dollar from its connection to the gold standard and making it a fiat currency, i.e. one where the government guarantees its value. The mindset was to a great deal captured by Ayn Rand's objectivism, where man is (or should be) driven by reason and self-interest, and where the economic system in greatest extent should be removed from its constraints. In the beginning of the 80's the Reagan administration started a long-going trend of deregulation towards a laissez-faire market economy where all trust was placed in Adam Smith's invisible hand. This means that the individual's self-interest is assumed to be good for the system as a whole, a trend that was continued by the head of Federal Reserve and Rand-disciple Alan Greenspan.

One reflection I make here is that the economic system seems to be lagging after the philosophical, scientific and technological revolutions. According to Dawlabani the Orange economic system starts to dominate first in late 20th century, several centuries after the industrial revolution and enlightenment, which is typically associated as being Orange in integral settings. Still, this may be accurate since also value systems dominating in a population do lag behind this way, and that the economic system should be at least somewhat aligned with this.

The period from the 80's to 2008 can be characterized as a gradual shift away from the Blue regulatory, stable and industry and work output-related Main street economy to an Orange, market-driven, growth-oriented and speculative Wall street economy. Here the brightest minds of the country were busy, not curing cancer or inventing new clean energy sources, but creating innovative financial instruments that had less and less to do with the real economy of Main street, i.e. with creating jobs and relating to the real value of e.g. houses. One of the above mentioned deregulation was the abolition of the Glass-Steagall Act that made it possible for commercial banks insured by the taxpayers to take part in risky speculations. When the housing bubble burst in 2008 it threatened to make the entire economic system collapse, which was avoided by the great bailout of the banks by the new Obama administration. But since then no real revolution or transition to a new system has been seen.

Green – equal distribution and democratization of information

So what is Dawlabani proposing as a solution and way forward for the American economy after this Orange collapse? Perhaps an economic system based on the Green 6th level value system?! Well, not really. The characteristics of the Green value system are introduced quite briefly in accordance with two themes:

Human bond and equal distributions, which is obviously about the unequal wealth distribution and the 99 percent that has been frequently discussed after the financial crisis. The theme is not very elaborated and is dismissed by Dawlabani rather sweepingly:

> The European Union is a good example of a system that champions Green economic policies as evidenced by their bloated social welfare programs. Green vMeme corporate practices have helped bring equality in pay to the worker, but that same system has taxed those corporations at such a high rate that innovation is often stifled. This system can unfairly burden a whole culture and bring it to the brink of financial disaster. (Dawlabani, 2013, p. 61)

The democratization of information, the second theme, is given considerably more attention and contains an interesting discussion on how the internet of things and the non-scarce nature of information have connected us globally and given us access to free information and paved way to open source collaborations. This has had consequences for the economy, e.g. in the media industry, where newspapers and magazines have gone out of business, peer-2-peer sharing of media, new business models such as crowdfunding have emerged and even gift based models (which could possibly be seen as purple mode economics).

Still, there is no consistent and functioning Green vMeme economic system described or discussed here. Shouldn't the Green economic system, whatever that is, have its cycle with all its phases? Shouldn't stages *not* be skipped?! Instead of elaborating on a green system as a solution to the orange problems, Dawlabani moves on and proposes a Yellow system, which he refers to as *Functional Capitalism*.

Yellow – functional capitalism

This value system is often characterized as being a synthesis of the healthy versions of all previous value systems, such as Orange emphasis of progression and applying scientific advances, Green concern for fair distribution and the environment, and Blue order and stability and so forth. Here one strives to integrate all perspectives rather than to see them as being in conflict with each other.

No such system exists yet on a national level. However, Dawlabani gives some concepts or design principles such as *Natural Design*, a Yellow concept based on insights from previous value systems adapted to the life conditions at hand, and *Distributed Innovation*, an application of *Natural Design* in the knowledge economy, that are practiced by the two companies Whole foods and Google that can serve as inspiration and example of economy at the Yellow level. The notion of *Conscious Capitalism*, as stated by Whole foods' CEO John Mackey, is described as integrating healthy aspects of Orange and Green values after an elaborate version of the triple bottom line: People, passion, purpose, profit and planet. And fueled with renewable energy. Dawlabani also discusses key politicians, economists and media personalities that are at that level in order to support the transition from Orange to Yellow.

Concluding, the struggle between the Blue and Orange value systems in the American economy I see as the most detailed and initiated part of Dawlabani's analysis. The previous two value systems, Purple and Red, are only briefly discussed and serves as a historic background, it would be great to have that more elaborated and related to other sources than the Spiral Dynamics framework itself. The Green value system, however, is in my view oversimplified. In order to integrate values at a higher level, the lower ones need to be accurately understood and described. And the key to do that, I believe, is to acquire a deeper understanding of the *life conditions* and problems that are associated with the Green value system and created by the Orange systems. Here I find the second book more elaborate.

Leading from the Emerging Future: From Ego-System to Eco-System Economies

In order to get more attuned with the challenges we face on a global level and beyond the economic system I find Otto Scharmer's and Katrin Kaufer's book *Leading from the Emerging Future: From Ego-System to Eco-System Economies* closer to reality, to the current challenges and the limitations of the current capitalist economy. The book comes out with a flying start:

> Finance. Food. Fuel. Water shortages. Resource scarcity. Climate chaos. Mass poverty. Mass migration. Fundamentalism. Terrorism. Financial oligarchies. We have entered an age of disruption. Yet the possibility of profound personal, societal, and global renewal has never been more real. Now is our time. (Scharmer and Kaufer, 2013, p. 1)

Scharmer and Kaufer are both economists and have their main focus in the lower right quadrant in AQAL terms, i.e. on systems, institutions and on global problems. They take a wide scope and list eight structural disconnects relating to nature, labor, capital, technology, leadership, consumption, coordination and ownership, which need to be addressed. But they argue that the disconnects and the challenges can be seen as symptoms of three major fault lines or divides on a psychological and cultural level; in our relationships with ourselves, in our relationships with each other, and finally in our relationships with nature and our planet.

The Developmental Framework of Scharmer and Kaufer

As Dawlabani, and this can also be seen as an integral theme, Scharmer and Kaufer present an evolutionary economic framework, a stage theory for socio-economic development. This has much resemblance with the Spiral dynamics framework, although it seems not to be related to psychological development according to the field of adult development. The stages are, however, associated to a certain mindset or core belief and mode of technology. They refer to the stages as Economy 0.0, 1.0, 2.0, 3.0 and 4.0 that seem to be in good correspondence with the Purple, (Red)/Blue, Orange, Green and the Yellow value systems, respectively, as briefly follows up to 3.0:

Society 0.0 is referred to as pre-agrarian, which seems to correspond to the purple value system in Spiral Dynamics where man is embedded in “mother nature”. The corresponding mindset is premodern awareness, typical of indigenous tribes.

Society 1.0 is seen as state-driven society with stability as its main focus. The description of the logic corresponds to the blue value system (the previous red value system seems to have no correspondence in Scharmer’s and Kaufer’s framework, or could be included in this 1.0 stage). This stage corresponds to a traditional awareness.

Society 2.0 is associated with the industrial revolution, the rise of business with competition on a de-regulated free market (laissez-fair) and mass-consumerism. The main challenge of the system is growth, clearly corresponding to Orange in Spiral Dynamics terms. Scharmer and Kaufer refer to this mindset as ego-centric awareness, which gives a hint that they see this as a non-desirable stage in itself, being main responsible for the above mentioned crises.

Society 3.0, or stakeholder-capitalism, is described as dealing fundamentally with negative externalities of the previous stage, such as poverty, exploitation of low-income workers and the environment. Examples are European style regulated social-market economy. Technological advancement is characterized by the second industrial revolution with oil, combustion engine and chemicals. The 3.0 mindset extends from the 2.0 self-interest to a stakeholder-centric awareness and the main logic of this society can be seen as being a reaction towards the previous 2.0 and dealing with its limitations:

> Measures to correct the problems of Society 2.0 include the introduction of labor rights, social security legislation, environmental protection, protectionist measures for farmers, and federal reserve banks that protect the national currency, all of which are designed to do the same thing: limit the unfettered market mechanism in areas where the negative externalities are dysfunctional and unacceptable. […] Stakeholder capitalism, or Society

> 3.0, as practiced in many countries, deals relatively well with the classical externalities through wealth redistribution, social security, environmental regulation, farm subsidies, and development aid. (Scharmer and Kaufer, 2013, p. 54)

Before going into the limitations of society 3.0 and moving on to the next stage, I will take a closer look at the most central problems that this stage is trying to address. It will be addressed in more detail due to its central importance to the question on the limits of the current economic system and of capitalism, and on possible ways forward.

The Challenges of the 3.0 Society or the Postmodern World

In Dawlabani's analysis the Green value system is only elaborated on with respect to one theme, the knowledge economy, but gives only brief attention to the second theme that I think is of greater importance here: the distributional or social aspects. A third theme, perhaps of even more importance and also not more than briefly mentioned by Dawlabani, is the environmental concern and focus on sustainability. Both these themes can be described in terms of being in conflict with the modern Orange value system and with its most fundamental premises of economic growth. Here follows a description of the two latter themes and challenges according to Scharmer and Kaufer, but also with some other sources that I find useful and illustrative.

Sustainability

Beginning with the aspect or theme of environmentalism or sustainability, the perhaps most fundamental premise of an Orange economy is that it should grow and the most obvious critique from an environmental or sustainability perspective is that there are limits to growth on a finite planet (Meadows, Meadows, Randers, Behrens III, 1972). In terms of ecological footprint we currently overshoot the planet's carrying capacity with 50 percent. This shift in perspective is sometimes referred to as going from an empty world to a full world (Costanza et al., 1997), where an Orange view of the world is one of abundance but Green views it as limited with a scarcity or recourses and a limited ability of the planet to absorb waste.

A common critique of the current market economy is that it fails to take into account externalizations, meaning that the environmental impact is not included in the price of a commodity such as an airline ticket that doesn't include the cost of the CO2 being emitted or the many ecosystem services that we take for granted. An ecosystem service is something that nature produces that is of value to us, such as fresh water, soil, the air we breathe or bees pollinating our plants. A response according to the Orange value system is to assign an economic value to these ecosystem services, which would also allow the economy to continue to grow since more things of value are added to the economy. Giving the ecosystem and its services a value would mean that they can be taken into considerations when we make decisions on whether we should exploit such a resource.

This commodification of nature and attempt to subordinate nature into the economy, which can be seen as an Orange or Society 2.0 logic, gets heavily criticized from many environmental activists and proponents, one such I find in George Monbiot (2014). Monbiot argues that giving things an economic value also means that it will be treated as any other exchangeable commodity instead of a necessity for our survival. It can also be argued that we reinforce the view of nature as instrumental, i.e. as something that is there for the sole purpose of being exploited by us. It is meaningful to talk about financial capital and natural capital, but they should be seen as non-commensurable – you can't eat money.

Other examples of insufficiencies in the 2.0 mode of business to adapt to life conditions of a full world are manufacturing and material flows. This was succinctly summarized by Robin Wood in his keynote speech at the IEC 2014:

> Linear economy: We dig holes on one side of the planet, we extract resources, we pump them through supply chains, then we go to the other side of the planet and in two years we deposit 98% of these precious resources in another hole. (Wood, 2014)

A typical 3.0 response to this this linear economy is to regulate and reduce the material use. Another alternative to the linear economy, a circular one, will be discussed in the description of Society 4.0.

Another aspect of sustainability of interest is energy, and using renewable energy is something almost everyone pays lip service to, but a transition from a society currently where roughly 85 percent of the global energy consumption comes from fossil fuels may be harder than one first could expect (Heinberg, 2009). In his *Crash Course* Chris Martenson (2014) emphasizes the close connection between increased energy consumption and economic growth, and where global oil extraction during the 00s has been at a constant level. Kjell Alelkett, president of ASPO, Association for the Study of Peak Oil and Gas, argues that the spike in oil prices in 2008 was a trigger to the financial crisis (Aleklett, 2012). In terms of energy we are possibly not only approaching a full world but one that is shrinking.

Fair Distribution Between and Within Cultures

After these examples of how the Orange system fails to address sustainability challenges and the planet's limits to growth, let's turn our attention to the distributional or social aspects of the economy. With Scharmer's and Kaufer's global outreach they give emphasis to what they refer to as the socio-economic divide. An obvious illustration is that the richest 1 percent own 40 percent of the world's wealth, even 48 percent according to more recent data (Oxfam, 2015), while half of the world's population own just 1 percent. Often it is described that capitalism and globalism implies that the wealthy world externalizes its real costs to the poor. Starvation is not a sign of lack of food, but rather of poor distribution.

Other arguments of the benefits of striving towards a more equal distribution, but within cultures, are found in *The Spirit Level* by Richard Wilkinson and Kate Pickett (2009) who investigate the relation between GDP and other variables that they argue are of more relevance, such as life expectancy, health and happiness. They all increase with increasing GDP up to a certain point when the relation gets weaker and the curve levels out. In the industrial world, dominated by the Orange value system and above, economic equality then becomes a better predictor of these indicators of a good life.

For these problems capitalism and market liberalism appear not to be positive forces. Rather, they produce larger gaps Scharmer and Kaufer argue with support from studies made by the International Labour Organization in 2008. This is also in line with the arguments made last year by Thomas Piketty in the widely debated *Capital in the Twenty-First Century* (2014), where he discusses the inequalities in income and wealth that has increased after 1975, refuting the claimed effect of the Reagan era's "trickle-down economics" with deregulations and tax-breaks for the already wealthy. Capitalism is great at producing new wealth but not at distributing it, Piketty argues as he proposes a global wealth tax to counteract this.

A way of dealing with the material and economic inequalities and a system where profit has become more important than creating jobs, basic income has been discussed in greater extent, although it being an old concept. And the concept of a sharing is not limited to information and knowledge, a *sharing economy* with couch surfing, sharing of tools, car rides and different services have been discussed and practiced more, not least due to the new possibilities of connecting on the web.

In conclusion, Scharmer and Kaufer show that the 3.0 economy of the Green value system is much about opposing and transcending the limitations of the Orange 2.0 market economy. It does so by problematizing economic growth as an intrinsic goal in itself and by stating that the economy should be of limited and subordinate nature instead of the opposite. And that it should also act as a means towards satisfying social needs and increasing economic equality.

Still, Scharmer and Kaufer do not consider it to be enough to deal with the current crises: "There are three essential limitations of Society 3.0: It is biased in favor of special-interest groups, it reacts mostly to negative externalities, and it has only a limited capacity for intentionally creating positive externalities" (Scharmer and Kaufer, 2013, p. 54). They dismiss what some argue, to go back to a 2.0 society, 1.0 or even 0.0 state of economy, and proposes a way forward, to a 4.0 society. But what would that look like and how would we reach it?

Society 4.0

Society 4.0, is characterized by co-creation and as being human- and life-centric. Money and the economy should serve the real economy and the well-being of all, and to be means to positive social change. Technological development, and more specifically the third industrial revolution (with renewable energy and information technology), is seen as a prerequisite to the 4.0 society. However, just as the economy, the information technology should be seen as being human-centric, i.e. means toward human well-being, growth and social creativity.

Where 3.0 can be seen as a reaction towards the problems of the previous stage and dealing with them separately, 4.0 offers a systems view and shift in perspective where the described problems are seen as symptoms of the divides described the introduction of the book. The shift in perspective is from problems to the underlying causes, to the system and inwards to ourselves. Thus, they argue that the challenges need to be addressed first on a personal/spiritual level, then on a relational and finally on an institutional level by creating social and cultural movements. When they go into the psychological processes necessary for change to take place they refer to *Theory U*, described in previous work by Scharmer (2009).

Sharmer and Kaufer gives several examples of how different interests are needed to be addressed and to work together instead of competing, for instance by addressing poverty and environmental issues at the same time. Here is a characterization of the 4.0 stage:

> In the emerging 4.0 stage of our economy, the natural self-interest of the players extends to a shared awareness of the eco-system. Eco-system awareness is an internalization of the views and concerns of other stakeholders in one's system. It requires people to develop the capacity to perceive problems from the perspective of others. The result is decisions and outcomes that benefit the whole system, not just a part of it. (Scharmer and Kaufer, 2013, p. 56)

When it comes to material flow, the natural response to the limitations of a linear economy is a circular one, where material flows are kept in closed loops, either in a natural cycle and totally degradable or in technical cycles where they can be processed and reused. This is referred to as the Cradle to cradle design principle by Michael Braungart and William McDonough (2009) or as circular economy, and is taken as an example by Scharmer and Kaufer as a way forward.

In conclusion, I think the strength in Scharmer's and Kaufer's book lies in its rich description on cases and way of overviewing the current challenges and limitation of our current system. They don't back down from the big challenges. The book has as its main broad focus the socio-economic issues of the lower right quadrant in AQAL terms, but aims for making the connection to the other quadrants in its emphasis on taking action (upper right quadrant), in organizing and doing it together as a culture (lower left), and on the personal, psychological and spiritual aspect (upper left), and that these aspects are interdependent: "The matrix suggests that the evolution of economic structures follows the evolution of human consciousness – or, to be more precise, that they are highly interdependent" (Scharmer and Kaufer, 2013, p. 239). However, the book does not refer to any theory from the field of adult development or integral theory in further elaborating on what they mean by evolution of consciousness, a connection that needs to be further addressed. One first step is to relate it to and compare it with Spiral Dynamics, which will be done in the following section.

A Comparison between the two Developmental Frameworks and with other Perspectives

Generally speaking, the two frameworks show a significant consistency in their description, but there are some differences in how they interpret and order historic and economic events. It may sound like an academic detail, but how things are ordered can have an effect on and be seen as a reflection of one's view on e.g. the financial crisis. Dawlabani sees the development of the US economic system in the last decades as in transition from blue to orange while Scharmer and Kaufer argues that it has moved from 2.0 (orange) towards 3.0 already after the great depression in the 1930's and then *regressing* during the Reagan years. "In the 1980's the neoliberal Reagan-Thatcher revolution began to move the country backward from 3.0 to 2.5, so to speak, by reshaping the institutional design in favor of deregulation, privatization, and tax reduction, particularly for the rich and super-rich" (Scharmer and Kaufer, 2013, p 58). Thus, their view of the current market oriented system as being a result of a regression is more problematizing than

Dawlabani's as they refer to 2.0 as an ego-system economy (although Ayn Rand herself would probably be ok with such a characterization).

Another inconsistency is that Dawlabani views the information revolution as belonging to the Green value system while Scharmer and Kaufer sees it as corresponding to Society 4.0 (the reverse relation holds to Google as a company that Dawlabani considers to be Yellow while Scharmer and Kaufer sees it as 3.0).

The examples above can be seen as illustrations of the difficulties of classifying different systems, economies, companies or design principles, at being at different stages. The Spiral Dynamics framework was firstly based on the study of individuals' values but is mostly employed in studying cultures. And Scharmer's and Kaufer's framework is not that stringently defined. Trying to classify concepts and systems, which can be seen as artefacts from a culture's certain value system, is all but simple and straightforward.

Scharmer and Kaufer offers, in contrast to Dawlabani, several case studies where they employ their framework in different cultural settings in addition to USA, such as Europe, Africa, China, Indonesia, India and Russia. Although it would be interesting to hear if Dawlabani or other proponents of Spiral Dynamics would agree with those descriptions, such as the interpretation that China can be seen as a 3.0 society and even on a path towards 4.0. Scharmer and Kaufer are also broader in their scope and see the economic system as very limited part of our society. Dawlabani's book seems to be more detailed and accurate regarding the description of what lead to the financial crisis, but I find Scharmer's and Kaufer's description of the grand challenges we face and the path forward as more useful.

I would also like to make a further connection between the developmental frameworks presented by Dawlabani and Scharmer and Kaufer, and a framework for sustainability that is more commonly referred to in mainstream discussions. Given these challenges and issues, an economy according to Society 4.0, or the Yellow value system, could be described as a synthesis and coordination of different spheres or dimensions, the most important being the economic, the social and the ecological. The most obvious framework to do so has been around since the 80s, the Brundtland commission's definition of sustainability (1987), where the economic, the social and the ecologic dimensions are taken into consideration and coordinated so that the needs of present generations are met without jeopardizing the needs of future generations. How this coordination is performed has long been discussed, in terms of whether they should be seen as three pillars (weak sustainability) or nested with the economic dimension subordinated the social dimension which in turn is subordinated the ecological (strong sustainability).

A few of my own suggestions on what could be regarded as Yellow economic systems are Tim Jackson's description of *Prosperity without Growth* (2009), where he proposes a route towards a sustainable economy. In academia the transdisciplinary subject of Ecological Economy (Costanza et al, 2007) has grown rapidly in interest, where it is argued, or rather demonstrated, how the economy needs to be subordinated to the ecological dimensions and to a full world of resource scarcity. Another good and balanced orientation and broad view on sustainability is also offered in *Garden Earth – From Hunter and Gatherers to Global Capitalism and Thereafter* by Gunnar Rundgren (2012).

Concluding, I find both books worthwhile reading and would recommend them to everyone who are interested in the future of economy. Although they differ in some details, I see them as consistent to each other and complementary, and they can aid for example those who want to broaden their interest from adult development or integral theory to a focus on the development of our societies and economic systems. They represent important steps towards a truly integral perspective on sustainability and the future of capitalism and our economic systems.

What about a Turquoise Economy?

Finally, a few words on what would be regarded as a Turquoise economy according to Spiral dynamics. Scharmer and Kaufer haven't proposed any society 5.0, but Dawlabani's gives some brief characteristics of what this might look like:

> When all the stakeholders identified in it are treated as *holistically interdependent*, a whole different set of values that is far more conscious begins to rise. Suddenly every stakeholder is meshed into an interwoven web that regards the planet as one ecosystem. This is the singular organism that all stakeholders plug onto to insure its long-term health. (Dawlabani, 2013, p. 257)

An underlying assumption in the definition of the Brundtland commission, as well as the basis for most discussions on sustainability in general and economy in particular, is that they are anthropocentric. Possibly, a Turquoise view would rather be based on a view on nature and the biosphere not as something out there for our purpose or something to take care of and to save, but as something we are.

Review of Integral Development

Schieffer, Alexander and Lessem, Ronnie. (2014). Integral Development. Realising the Transformative Potential of Individuals, Organisations and Societies, London: Ashgate Gower.

Reviewed by Wendelin Küpers[1]

We are living in a transformative time facing radical challenges of and in urgent need for a more integral understanding of development, conceptually and critically that are opening up genuinely new pathways for thinking and acting. In their book Alexander Schieffer and Ronnie Lessem offer a contribution which does this excellently, and in detailed ways.

For quite some time the authors of this comprehensive book have been engaged in developing and putting into practice and what they call “Integral Worlds approach,” articulated in several books, articles and projects. Their Integral Worlds is a much to be welcomed project for understanding and consciously designing evolving human systems.

In this timely and useful publication they show how a more considered and complex comprehension of development, qualified as an integral one, looks like.

Offering multiple entry points into the book and approaching integral development they invite the reader to a journey, for which they offer rationales, maps with compasses as well as orientating contents, guiding questions and illustrating cases as well as conceptual tables and figures.

Accordingly, their presentation of integral development is systematic and principled, methodologically and normatively, and this integrating style of thought exemplifies itself what the book is all about.

Starting by contextualising and problematizing non-integral development and the need for more integrative understandings and realisations of the same, they are setting the scene for the following detailing chapters, organised in distinct but interrelated main parts.

While the first part problematizes the divided worlds we are in and the need for renewing human development, the second part presents new integral perspectives on human development. The subsequent parts outline in detail the four directions and realms of an integral development (ranging from restoring life in nature and community, regenerating meaning via culture and

spirituality, to reframing knowledge via science, systems and technology up to rebuilding infrastructure and institutions via enterprise and economics. In particular, the authors invited to travel through the 'Southern' realm of relationship (Part III), the 'Eastern' realm of inspiration (Part IV), the 'Northern' realm of knowledge (Part V) and the 'Western' realm of action (Part VI).

The final part reviews the integral development journey and while following the idea of a 'unity in diversity', outlies perspectives on an integral university.

For the authors the book and its framework are responding to what they call "profound civilisation crises," marking a comprehensive shift of individual and collective experiences.

What the book offers is an "understanding-learning-research-education-action-journey" that claims to support the evolution and co-development towards a more integrated paradigm. Thus, it provides a comprehensive overview on significant dimensions for a more integral understanding and enactment of development.

Re- and deconstructing and diagnosing critically disintegrative patterns of past and current developments (and its underlying assumptions) and mono-cultural dominances are revealed.

Integrating design principles brings together all those important realms, rounds, rhythms and realities on local and global levels, from self, organisation, societies, and world, to approach and process development issues and capacities that need to be built into future development work. Accordingly, their differentiated explored, comprehensive fields of developments are ranging from self-development, organisational development, societal development up to, ultimately, integrated practice, allowing various synergistic crossings.

For them whatever the particular calling and challenge a reader might experience or face, developmental issue can be approached integrally. Consequently, their Integral Development framework helps to move starting (a) from a particular reality; (b) via all key realms; (c) adopting a fully integral rhythm; and (d) adopting individual, organisational and societal rounds, and thereby ultimately contributing to new global perspectives.

However, this starting point and logic as well as the implicit status of responsibility tends to underestimate the same of collective actors/agency and institutions/systems (overburdens individuals and local communities).

> The responsibility in an Integral Development paradigm lies not any longer primarily with abstract political systems, economics, science and technology. Rather the responsibility for development lies with the people living within a particular context who see a need or follow a desire for development. The process, we are proposing, increases the 'response-ability' of each individual development agent. (p. 128)

This specific focus on humans and humanity, appears as a revived humanism. Such humano-centric perspective might be seen as inclining towards a certain 'anthropocentric' orientation, which is in danger of not considering sufficiently that development is not (only) for human flourishing, but involves other living beings, animals, and even anorganic materialities.

As we are living in and coming to grips with the unprecedented challenges of the era of the *Anthropocene*, and for facing the ecological crisis and its underlying anthropocentrism, a anthro-de-centred orientation calls to re-situate the 'anthropos' and its development in a relational nexus co-constituted not only by its humans (who are in fact 'humanimals'). Rather development is always already and need to be more mindfully related to 'other – than-human-beings', including all those material dynamics of 'physicalities-cum-culturalities' involved, and vice versa.

What is needed are integral understandings of the embodied nexus of the *in(ter-)between* of 'materio~socio~cultural' phenomena, 'contextures' and expressions of corresponding relational practices and its 'non-/other-+-human' meanings (Küpers, 2016; Ingold, 2000).

Moving beyond naturalism and constructionism as well as physicalist empiricism and metaphysical idealism, we need to integrate an inter-corporeity of 'self-other-things' also in and of defracted organizing with an ethos of engaged letting-go or "Gelassenheit**" (**Küpers, 2016).

An integral development in this extended sense becomes even more relevant as the potentially catastrophic and irreversible circumstances for human and non-human nature due to non-integral progress and growth-dependencies that become increasingly evident.

Conceptually and methodologically the ordering of contents to categories might be seen as contingent or different. What about overlaps between, for example inspiration – relationship, culture-community or knowledge / action?

With regard to starting point, their plea for progressing inside out, step by step might be complemented by out-side in moves and non-linear unfoldments.

What is dialectically appealing for readers are their guiding questions, clear illustrating tables and figures, providing overview and summary as well as inviting the reader to reflect and process the thought-provoking and action-inviting contents!

Their generic design is different from other representations, (e.g. compared to Wilber as they place action/behaviour or culture and systems differently) and in term of discourse they call for developing even more connectivities to existing integral models.

Critically, some claims are less developed than one might wish and some more reflexive (self-) critical discernments could have been elaborated. What are limitations and problematic aspects of their presented approach? How could development be understood differently? What is or cannot be integrated in their conceptualisation or realisation of integration? Basically, the authors are optimistic that the move beyond the prevailing disintegration and imbalanced approach towards a new integrating and balanced understanding of development is possible. But what about developments that are not progress along the outlined principles? What about liminalities, conflicts, incompatibilities between sub-developmental moves? How can creative tensions between the outlined areas and realms be used for a transformative re-evolution that also moves via leaps, discontinuous processes? What would a “bounded integrality” (Küpers et al. 2010) mean for development?

How can an non-objectifying ethos of careful and ‘engaged letting-go” (‘Gelassenheit’) be connected to the envisioned Integral Development that is realizing the “Transformative Potential of Individuals, Organizations and Societies?”

Which habitual, representational and appropriating orientations as well as corresponding projection and totalizing closures of enframing and actions need to be abandoned, for accomplishing the aspired integral development?

What role may a receptive waiting and listening, thus more an ‘active non-doing’ in relation to things and what ‘matters’ play, rather than a willing and controlling business, including if this claims to be an integral one?

How can modes of poetic relations, intermediated via a presencing, atmospheric sensitivity and proto-meditative tuning and possibilities for the be(com)ing of an ‘Othering’ be cultivated?

One area or link for future research on integral development may be practical wisdom. How can an integral development be qualified as a wise one? What role might a critical poetic phrónêsis an embodied, wise and artful practice (Küpers, 2013) mean for future integral developments?

Altogether, Alexander Schieffer and Ronnie Lessem have provided a richly insightful and highly readable look at how an integral development can be not only per- and conceived, but also put into practice.

Overall, this book is in a way a culmination of what the authors have done and an aspirational, programmatic and practical agenda what needs to be done to better conceptualize and enact more integral forms of development.

In this way and in the proper spirit of ‘Gelassenheit’ they contribute to the r-evolutionary unfoldment of integral thinking and acting, for which I hoped that it will find a wide appeal, and resonant readership.

Readers’, including me, are certainly looking forward to the next iterations and descriptions of their project, whose value, as consists in integrating contents, program and style his book calls for and itself exemplifies.

Their work is offering real hope for a proactive orientation and constructive response to the enormous and unprecedented challenges of our age and for a more integral future to come.

Introduction

In reviewing a book like this, I realize there are many challenges. It is a business book, yet there is extensive theory incorporated into it. Written for a mainstream business audience, it also brings anticipation to those looking for adult development work to get a stronger foothold into society. The authors aim high, intending to set a new benchmark for leadership development work. So there can be intense scrutiny of how the argument is put together. In this review, I attempt to give voice to all of these tensions as I weave my way through conveying my impressions of it.

To begin this review, I take an overview of some academic work as a way of contextualizing how such an integrative move can be approached. There have been many attempts to create an integrated framework for first understanding leadership, and then from this, to be able to do something about developing it. For example, Rost (1991) stated that "no one has presented an articulated school of leadership that integrates our understanding of leadership into a holistic framework" (p. 9). Subsequent scholars have taken up the challenge with varying perceptions of the results. Goethals and Sorenson (2006) undertook *The Quest for a General Theory of Leadership*, without coming to a consensus. Harvey and Riggio (2011) explored *Leadership Studies: The Dialogue of Disciplines*, examining how diverse disciplines such as political science, psychology and history among others can give insights into leadership. Kellerman (2012) talks about *The End of Leadership* as a way of trying to get us past the chaos of our multiple conceptions. She estimates 1400 definitions of leadership, along with 44 theories about it.[2] It appears that scholars are not coming to an integrated framework anytime soon.

If all these scholars have struggled to do this, what can this tell us? It might be that approaching it from the academic orientation comes with inherent limits. One of these limits could be from being more immersed in observing and analyzing than doing and reflecting. It could come from the type of training one receives to be an academic, with the disciplinary, rational and analytical enculturation of the profession. The postmodern demand to give equal

voice to diverse perspectives could play into it. It could even be that the deeper one looks and the more granularity in the focus, the forest can get lost for the trees.

From this it can be worth looking to see if something new, at least a step in the direction we are looking, can come from beyond the academic world. Being outside of the constraints of the academy has its advantages. While many of us have encountered casual, popular attempts to bring good ideas into practice, we have often been disappointed. However, at its best, being free of academic constraints allows for a freedom of expression that can generate breakthroughs of expression, enabling complex, post-conventional ideas get a foothold in the conventional consciousness of mainstream society.

The challenge here is that it can be rare to find a sufficiently reflective practitioner (Schön, 1983) who can give clear enough voice to his or her experience in order to share that with others. Few business leaders are sufficiently well versed in theory to describe their experience in terms that would meet the scholar’s desire for conceptual rigor and clarity. Among consultants, Bill Joiner (Joiner & Josephs, 2007) comes to mind as someone who has aimed to present an integral view of leadership and its development. Bill Torbert (2004), as an academic and consultant practitioner, has also done a great deal to bridge the gap in this area. Doing a simple search on Amazon for ‘integral leadership’ generates plenty of results (including the book under review here), with most appearing to my view as either being the usual suspects, specialized or related topics. However, my perception is that none of these works has penetrated deeply into the mainstream business discourse.

It is in this context that Anderson and Adams (2016) have come forward with their version of an integrated framework for mastering leadership. As consultants with a reflective turn and a strong capacity for theoretical integration, they have put together a book that explicitly takes on the challenge to come up with an integrated framework for leadership. The questions that I wish to address in this review are primarily about how this book makes its case for this framework.

Context

My own study of leadership has been much more in the academic context, although in recent years this has translated into practice at facilitating its development in others. With an aim at transparency and disclosure, much of this practice has come in conjunction with the use of the framework and tools described in this book. I first encountered Bob Anderson in 2003 on a conference call and then in 2005 through an interview with Russ Volckmann in Integral Leadership Review. This led to taking the certification in The Leadership Circle that year and beginning the long journey of learning how to make good use of it. Part of that journey has also included becoming associated as well with Bill Adams and the Full Circle Group (a consulting business built on the TLC framework) in 2010.

I should also say that I have been using the main assessment instrument from the framework, The Leadership Circle Profile (TLCP), in the classroom for a continuing education leadership course and with various client programs over the past seven years. I have also in the past year begun to lead certification programs for consultants and coaches wanting to be licensed to use TLCP in their work. This leads to two things relevant to this review. One is that I am deeply familiar with the framework and tools in a variety of contexts (I have seen something like 300 profiles and coached dozens of leaders with it) so I can speak from experience in relation to many of the descriptions and claims in the book.

The second is that while on the one hand I might be biased in favor of the book for a variety of practical reasons, I also come with high expectations. Nothing that is in this book is new to me and I was not expecting it to be. This book is a combination of many of the arguments, stories, research and implications that have been the core fabric of the TLC business and community of practice as long as I have been associated with it.

Before getting to a brief summary of the contents of the book, it is important to make some remarks about who is the intended audience for the book. This book is not meant to be an academic treatise on the subject, even though it is backed by extensive theoretical sophistication. This book is written for practitioners of leadership, “for leaders swimming in complexity, wanting and needing to thrive, knowing it could be different … also for leaders who are thriving in complexity and are hoping to teach others how to do the same” (pp. xxi-xxii). From this it appears to me that the aims of this book are primarily *pragmatic*. Thus the tone, tempo and structure of the book have this aim and audience in mind. For my review, I aim to examine a variety of issues around how this pragmatic approach shapes the book.

Another positioning that Anderson and Adams take in their introduction is to call their work “the first *Universal Model of Leadership* to emerge in the field” (p. xxii, italics and capitalization in the original). This is a bold claim and the authors acknowledge as much. Some of the opening references in this review hint at the breadth of other considerations possible when the term “universal” is invoked. Within these two contexts, the academic search for a comprehensive, integrated, framework for leadership and the pragmatic needs of organizational leaders, I will also examine how this book makes its case for this claim.

I want to reflect further for a moment on this claim and the positioning of the book as an integrated framework. This is related to the issue of integrative moves per se. One of the authors (Bob) describes how he “decided to meet, learn from, and work closely with many of the leading thinkers and researchers in the field of leadership” (p. xxiii) and from this saw that “the field wasn’t integrated” and so “set out to integrate it” (p. xxiii). Any such integrating move is subject to a number of constraints. Anderson (2006) discusses the tension between the synthetic nature of such integrative theoretical ventures and the need for humor, humility and openness to surprise. There is also the challenge of an unspoken set of hermeneutic horizons of preunderstanding (Palmer, 1969) that, when not acknowledged or reflected upon as constraints, can contribute to a totalizing orientation where contrary data can be filtered out or re-interpreted to fit the model.[3]

At the same time, any (vertical) developmental move aimed at taking a diverse set of constructs and conceptions and weaving them together in a manner that helps to illuminate a field of experience and phenomenon from a higher level of development so that it makes it accessible for a conventional audience can be considered as integrative.

---

[3] This critique has been aimed at Wilber’s AQAL integral model in particular. It is a natural enough tendency that many of us have been conditioned to take as a given aspect of such work.

Overview

Anderson and Adams begin with an introduction aimed to contextualize their work. It is a nice mix of stories, personal reflections and journeys with some orientation to the purposes and theoretical background supporting the book. They even have made a free version of the TLCP available for readers (self only, no evaluators included) to help anchor some of the concepts and examples to personal experience.

The book is laid out in two parts. The first few chapters set out to make a business case for the framework. Once this has been established, the second half then outlines the nature of the journey to greater leadership effectiveness. This is done over 13 chapters briefly described here.

Chapter one, *The Promise of Leadership: Meeting the High Bar of Expectations*, sets out the agenda for leadership and the related expectations. It notes the explicit expectations such as specific outcomes that roles bring, as well as the implicit expectations like competence, commitment and providing meaning and direction. Together these create a very high bar for leadership. They describe four 'universal' promises around leadership; setting direction and giving meaning, engaging stakeholders and holding them accountable, ensuring focus and execution, and leading effectively. Together these make up the leadership agenda.

Chapter two, *Leadership Effectiveness and Business Performance: The Primary Competitive Advantage* lays out a research project undertaken by TLC to determine the relationship between these two key constructs. An additional set of survey questions was constructed and added on to the TLCP survey that measured business performance. They show that the top 10% of leaders, in terms of this business performance index, scored on average in the 80th percentile on leadership effectiveness, while the bottom 10% of leaders scored at only the 30th percentile. (They also note comparable results from the research of Zenger and Folkman (Zenger, Folkman, & Edinger, 2009)). Having established the impact of leadership effectiveness, they then show how they can measure a leadership quotient by dividing leadership effectiveness by ineffectiveness.[4] This simple formula can provide insight into the competitive advantage effective leadership can provide. The chapter also goes into the collective leadership effectiveness as being critical for business performance.

Chapter three, *Mastery and Maturity, Consciousness and Complexity: The Leadership Development Agenda* begins to describe the field of adult cognitive development and how it relates to the agenda of leadership. They introduce this by talking about the outer game of leadership being made up of processes and competencies, while the inner game is about consciousness. They also give a long list of examples of literature that emphasize the view that the inner game runs the outer game. They then give a list of premises, that; structure determines performance, you are a structure, consciousness is the operating system of performance and that to achieve higher performance, you must be restructured. These are linked to the relationship between consciousness and complexity, the basic theme being to lead in the face of growing complexity you need to have an adequate complexity of mind to do this. This then forms the core argument of their view on the essence of leadership effectiveness and its development.

---

[4] In this section of the book they focus on using only the leadership effectiveness scores for this. There is also a further relationship between the upper and lower halves of the TLCP related to this formula. I also make some comments on the leadership effectiveness survey in my discussion.

Chapter four, *Stages of Development: The Backbone of the Universal Model of Leadership* takes this a step further. It goes into Robert Kegan's (1982, 1994) model of adult development and shows how it relates to the TLCP. The labels are adapted to the profile, with the socialized mind becoming the reactive half of the profile, and the self-authoring mind becoming the creative upper half of the profile.[5] Figure 4.4 shows the relationship between stages of development and leadership effectiveness, making a curve that is utilized later as well to show parallels with other facets of the framework.[6] The chapter also places identity at the core of the consciousness development framework.

Chapter five, *Five Levels of Leadership: Structures of Mind and Performance* goes through more detailed descriptions of the conception of vertical development stages and how they look in relation to leadership. They spend a lot of time showing how the socialized/reactive mind is linked to a set of beliefs that are measured in the TLCP and then how these reactive tendencies are negatively correlated with leadership effectiveness. In a similar manner, the self-authoring/creative competencies are linked to the upper half of the profile and shown to correlate very positively with leadership effectiveness. Brief descriptions of integral and unitive stages of consciousness are also included.

Chapter six, *The Universal Model and Metrics: Global Leadership, Cross-Cultural, and Gender Application* goes into the full range of application of the framework, research and relevance to questions of cultural diversity and gender. The chapter describes the dynamics that are woven through in the profile between the different dimensions.[7] There is also some interesting data on gender differences, with women being seen as significantly more caring than men, as well as generally scoring higher on the upper creative dimensions. They also present the research done on the relationship between stage development and TLCP that indicates a clear correlation between higher stage development scores and higher creative competency scores. As well, this chapter provides the data that the authors base their use of the term universal on. Their examination of how leadership effectiveness is described in diverse cultural settings supports the view that this framework translates around the globe.

Chapter seven, *The Leadership System: The Central Organizing System* describes the larger set of six systems that are relevant for organizational effectiveness, with leadership sitting in the center of this system. This chapter also contains some extended case studies that help flesh out how the application of the framework looks in practice. One in particular is an extended description of a leader and his team over a number of years and through significant changes in conditions. This is a very illustrative case, showing the ups and down over time and the impact a leader can have on business performance. They also use this to introduce the larger leadership system built on the framework.

---

[5] It should be emphasized that TLC is very clear that theirs is not a developmental measure. The upper and lower halves of the profile are designed to be grounded in these distinctions of Kegan's, without making any claims to be measuring them.

[6] It occurs again in relation to the stage development research. As a note, I have had access to the data set used for this and was able to replicate this figure.

[7] I can say as a practitioner that these dynamics are very useful and insightful for clients to see the impact of certain limiting beliefs and behaviors.

Chapter eight, *Reactive Leadership: An Insufficient Triumph of Development* begins a section of chapters that go into more depth and detail about the leadership journey. This chapter describes the nature of this stage of development, through a number of examples of how leaders came to realize that their behaviors were based on limiting assumptions based on safety rather than purpose. This is characterized as an anxiety management system where a problem or threat generates a fear, which leads to a reaction, which aims to alleviate the problem. The limitation of this structure is that once the problem goes down, so does the fear and thus the reaction. In the end, equilibrium is maintained and performance is limited.

Chapter nine, *Reactive Leadership at Work: From Patriarchy to Partnership* continues the theme set out in the previous chapter and links it to more in depth descriptions of the three main personality structures used in the reactive styles part of the TLCP. Based on Karen Horney's (1945) work, the TLCP framework describes complying, protecting and controlling orientations. The gifts or strengths of these are labeled heart, head and will. How these gifts get hung up on reactive operating structures is the key distinction they make. They also show how the natural outcomes of these reactive tendencies are to create patriarchal organizational systems and cultures.

Chapter ten, *Creative Leadership: Fulfilling the Promise of Leadership* moves on to the next stage of the journey. The journey to this stage is framed in terms of Joseph Campbell's (1991) description of the hero's journey. Once there, the process driving behavior is contrasted with the anxiety management system of the reactive mind as starting with purpose and vision, leading to passion and action. This virtuous cycle can enable sustainable growth. The restructuring of identity beliefs is shown to fuel this shift. This is also described in relation to how distinguishing the reactive elements and undertaking the practices described in the next chapter, a leader can move to the related area of the upper half (e.g. controlling can move to achieving).

Chapter eleven, *Six Leadership Practices: Spiritual Bootcamp for Leaders* does just as this title suggests; laying out six practices that all aim at supporting the developmental journey laid out in the previous chapters: Discerning purpose, distilling vision, knowing your doubts and fears, engage in authentic, courageous dialogue, develop intuition, open to inspiration and think systemically.

Chapter twelve, *Integral Leadership: Built for Complexity, Designed for Transformation* takes into account that a small but hopefully growing cadre of leaders are actually entering into this next stage, where they shift their relationship to not only leadership, but also to their sense of identity and understanding of the journey of development itself. Reference is made again to the stage score research, showing an aggregate profile of leaders who scored in this range as being highly in the upper creative half of the circle. Harvesting shadow elements of our identity is described as a key part of how the hero's journey shows up in this transition.

Chapter thirteen, *Unity: Journey's End, development Turned Upside Down* closes the book by questioning some of the very foundations upon which the framework is built. At the same time, it points to the authors' sense of purpose and meaning behind all of the work they have done. Grounding in various spiritual traditions is referred to as a way to describe this stage where ego is not developed, but surrendered. Two arguments are made for development despite the description of unity consciousness as making all of this irrelevant. One is that you still need to live in the world and need to use a structure of mind compete with competencies etc. to do this. The second reason given is that only a mature ego can be surrendered.

Two appendixes close out the book, one listing all of the definitions of dimensions in TLCP. The second shows a long list of theorists whose work contributed to this integrated framework.

Discussion

Kudos

Given this brief and basic description of the book, what can be said about it? The claim of being an integrative framework is justified. My belief for this comes from thinking about what theories and practices are worth including in such an integration, if as noted in the introduction, there are 44 theories of leadership. After spending 20 years studying the field, I find that the theories covered in this book tend to address perspectives on the topic that I view as worthy of inclusion (although I can imagine some differences in emphasis of course). Given the pragmatic, practitioner orientation the book is aimed at, the framework does indeed integrate a great number of theories, models and research from both academics and practitioners in the field of leadership in a very elegant and useful manner. (The appendix mentioned above describes the work of over 50 theorists whose work has been integrated into this framework). A good description of this is found when they write that TLCP

> and Universal Model integrate the best of Cognitive and Rational Emotive Psychology, within the Type framework at various Stages of Development, and relate all of this to what we have learned from the field of Leadership and Organizational Development about what works and what does not. (p. 198. Capitalization in the original).

One thing in particular that I want to give credit for is that Anderson and Adams do not fall prey to the typical tendency present in so many books in the field of creating a simple contrast between an old, bad version of leadership and a good new one we should all aspire to. Instead they lay out a clear developmental trajectory, how it applies to leadership and how each stage has its place and role in our growth and functioning as leaders. While this is not new, (in addition to the work of Torbert (2004) and Joiner and Josephs (2007) there is a growing body of leadership books based on developmental frameworks), they do a very good job of deeply developing and illustrating each stage, the transition processes and how they are relevant in a business context.

They also do a good job of presenting practices aimed to provide a good balance of challenge and support for leaders inspired by the vision and journey laid out in the book. While at first reading these practices can appear to fall prey to the critique Kegan (1994) makes of leadership literature by assuming a self-authoring mindset in order to achieve them, a closer reading shows that they are contextualized to actually help leaders use them as practices rather than as prescriptions. As practices, they can be used as a tool for growth rather than a measure of a standard with implicit requirements.

As a package for business leaders and consultants, the book gets the core message across clearly. The development of leadership effectiveness, and with it improved business performance, is linked to personal growth and development. Not just development as a generic term, but as a specific path of maturing the structure running our meaning making capacity. Getting this message across so powerfully is, in my view, the core achievement of this book.

Critiques

The critiques that arise for me need to be placed in context. As noted above, this book is written with a pragmatic lens. Not only that, I believe it is written primarily for an audience who the authors believe will read it with a conventional mind. The issues I have with the text are things that are more likely to appear relevant for a post conventional mind and or those with domain specific knowledge of adult development theory.

Along with this is a tension that I see goes along with the choice of writing style for the intended audience. I believe there is a desire to have greater market penetration for the core message of developmental growth being at the heart of leadership effectiveness than has been achieved by others. While I am happy to see this happen, I recognize that it comes with these certain tensions.

The primary framing for this tension for me is related to what Sara Ross (2008) wrote as the casual use of formal theories. Reading this text, there are sections of it where, to the knowledgeable eye, it could appear that the authors use theory casually. What I believe is more the case is that they use it implicitly and by not making sufficient acknowledgements of the tension that comes with simplifying for the intended audience, they leave themselves open to appear to the post conventional and domain knowledgeable mind that they use theory casually.

My first critique comes from tripping over some math when the authors begin describing their stage development research (p. 107). They use the work of Zenger and Folkman (2009) as a comparative set of research that also aims to understand the link between leadership effectiveness and business performance. The basic claim from both sources is that increases in leadership effectiveness as measured by a good 360 feedback instrument correlate powerfully with bottom line results, or increased profitability.

The question that arose for me was to what *degree* do “extraordinary leaders” (defined as performing at the 80th percentile or better on leadership effectiveness scores) actually bring these better results? Anderson and Adams claim a six-fold multiple for this. Digging around, I came to see that Zenger and Folkman (2014; 2009) talk about doubling profits. This difference of degree caught my attention and led to some extensive detective work to find its source. What I found was that Zenger and Folkman’s data on financial performance was reporting on the *average* per leader. This was only made explicit in their 2014 article, while in the earlier presentation of their research it was implied. Anderson and Adams interpreted the financial performance data as being an *aggregate* of the leaders’ performance in the lowest, middle and highest performing categories. Thus this difference between average and aggregate led to the differences in degree I noted above. I am sure that the reality is even more complex, with many possible factors influencing business performance. However, it is clear, and makes sense, that increased leadership effectiveness translates into increased business performance.

Moving on to a second critique, I was also confused by some of Anderson and Adams' use of developmental labels and statistics on the distribution of leaders across developmental levels. One issue I had here is how the authors have presented claims around findings from "the field of Adult Stages of Development" (p. 107. Capitalization in the original), as if there is clear consensus among theorists in the field.[8] This makes it simple and clear for the conventional business reader for sure, but it also misrepresents the actual diversity and ongoing dialogue about how stage models are actually related to each other, where stages can be sliced and for what purposes, etc. The authors have done their homework and thought deeply about these issues; I know this from personal experience. A simple acknowledgement in the text that *they* have made decisions and judgment calls on how to put this diverse body of theories together instead of an appeal to the authority of "the field of adult stages of development" would have been nice and explicitly acknowledged their implicit role in the presentation of this material.

I have some smaller critiques as well. The degree of repetition in the book became a bit too visible for me at times. Not only were phrases and sections of text repeated, but many figures appeared more times than I felt were necessary to get the point across. In the end, I believe that the book could have been cut by one third and made all the points necessary to present the framework and journey in a comprehensive manner.

A critique can also be made around how they support their claims in relation to leadership effectiveness. In the broader field of leadership studies this construct has been researched extensively (see for example the work of Fiedler, Bolman, Hogan, Yukl and others). In the TLC framework, leadership effectiveness is constructed as a measure based on five questions that are part of every TLCP. A description of the sources drawn on for this set of questions is not included in the book, and something around how this key measure was constructed would have been helpful to support the core argument.

My final point of critique relates to the label "integrative framework" presented in this model. It is really an integration of two key elements; leadership effectiveness and consciousness development. Beyond this it also integrates a host of other theoretical influences. So it is integrative. Using the term *universal* goes beyond this. While Anderson and Adams do point to how cross cultural results lead them to claim this universality, the scope of work referred to in the opening remarks, along with a sense of *American* style of self-promotional language, (rubbing the wrong way on my Canadian and European sensibilities), give me the impression that the claim is a bit of a stretch.

---

[8] They list their *creative* label as comparable with Cook-Greuter's *individualist* level and Kegan's *self-authoring* stage. My understanding is that Kegan's self-authoring is his 4th order, and that Cook-Greuter's (as well as Loevinger, Torbert, Joiner and Josephs, although with different labels) individualist level is equivalent with Kegan's 4/5 order. Kegan's 4th level is equated with the achiever stage in Cook-Greuter, Torbert and Joiner and Joseph's research.
In regard to the statistics of 20% being at the creative level or higher, again, I have seen diverse statistics around this, which are very much dependent on exactly where a person is deciding to slice things. I believe that the key is related to the above, the implicit choice that Anderson and Adams have made about how to position their creative dimension is key, yet how it is expressed could lead to confusion.

Conclusions

This book is clearly designed as a pragmatic approach for a mainstream practitioner market of leaders, those who want to be leaders in business and the coaches and consultants who work with them. For this audience, the claim to have found the "universal" model for leadership development will be on target. I believe it is a clear step up from the vast majority of approaches to leadership and its development on the market today. However, for those who are aware of the larger field of leadership studies, the claim to universality could irritate.

If I had been an editor for this book, there are some key things I would have strongly recommended to the authors. One would be to tone down or better frame their use of assertive language claims. A second involves the desire to see more polishing on the text in terms of clarity and better support for key aspects of the argument. Along with this, some explicit acknowledgment of their own judgment calls would help make the book that touch more solid it could use in places. The degree of repetition, while possibly helpful for some readers, could get tiring for others. I believe the same case could be made with only two thirds of the text and figures in the book.

None of these critiques take away from my perception that the book does manage to do what it sets out to; integrate key themes of leadership effectiveness and business performance with how they relate to the journey through maturing structures of cognitive development.

Response to Reams Review

Robert Anderson[1] and William Adams[2]

We would like to thank Jonathan Reams for his balanced and thoughtful review of *Mastering Leadership*. We think you capture well the intention and the challenge of this book. This book was written for business leaders and the practitioner audience with the intention to make complex theory and research business relevant through practical application. We endeavored to make this knowledge accessible to those not steeped in developmental theory and research, while also doing justice to the underlying complexity of the theory. At the same time, we want to bring home the significance of this body of work in a way that moves a developmental approach to leadership development to the center stage. In our opinion, vertical development is not yet mainstream (far from it), and it needs to become best practice.

We feel you did a very accurate job of summarizing the major focus of each chapter and the book as a whole. We especially appreciated your acknowledgement (from your 20 years of reading the field) that our theoretical framework integrates well the frameworks and research you find most relevant and useful. You also acknowledge, as the core achievement of this book, how we have integrated all this leadership and psychological theory into a well-described developmental framework.

Your critique of our interpretation of the Zenger-Folkman research is spot on. We made a mistake. In reading from their book, it is not specified that the middle percentiles are average performance. We mistakenly believed these to be aggregated performance numbers. Two-fold outperformance is correct, not six-fold. The argument we made is directionally correct. Leaders who measure in the top 10 to 20 percentile groups on a good 360 assessment are likely to significantly outperform the average.

You also raise the question of how we arrived at the conclusion that 20% of leaders are operating at Creative or higher. In describing how we came to this, let us set some context: There is a difference between *thought leadership* and *practice leadership*. We are practice leaders, not thought leaders, in the area of developmental theory. Our work serves as a bridge between theory and application, with the focus being on application. We profoundly value the contribution of Bob Kegan, Lisa Lahey, Susanne Cook-Greuter, Bill Torbert, Josephs and Joiner and so many others who are pioneering this most important research. We are not doing primary research and theory creation in this area, and do not represent ourselves as such. We are practice leaders who are working to faithfully integrate and apply the seminal work of developmental thought leaders. This book is written from that perspective. We reserve the right to get smarter and we believe very much that we have to be directionally accurate in all of our models and work. We consider ourselves learners who, through application, move the field forward.

As practice leaders, we have years of experience attempting to explain and apply these models in ways that gain traction with business leaders and that are experienced as business relevant. While very relevant to this audience of integrally and developmentally informed readers, an in depth discussion of theory would distract many business leaders from getting the full import of understanding their leadership through the lens of a developmental framework. Therefore, in our work with leaders, and in our book, we make core distinctions. The key distinction we make (relevant to the business leader audience) is the movement from being primarily authored by others to being primarily authored by self. In other words, the shift from Reactive to Creative is to become self-authored. We also equate the move into self-authorship as the primary work in shifting from conventional to post-conventional leadership. From our experience, venturing any deeper into the complexity and nuances of developmental theory becomes a trap with most business audiences and takes away from the development agenda we are working for them to adopt. *Mastering Leadership* is written from this perspective.

We have always conceptualized Creative Leadership as inclusive of levels 4 and 4.5. At full maturity it is green, Individualist, Pluralist, Catalyst. It evolves through Level 4 (Achiever, Self-authoring) and becomes fully Creative at the first post-conventional stage. Mature Creative leadership, therefore is early post-conventional. Levels beyond that are Integral and Unitive in our model. We see this as consistent with various adult development theories and accessible framing for a business audience, as well as for practitioners who are applying this work in their practice. We also think it is consistent with our practice experience and the emerging research.

Experience: We have a great deal of experience coaching and consulting to Achiever level leaders. While there is a marked increase in their perspective taking capacity (over the Expert), we find that this is still very much maturing. Many/most are still quite subject to the kind of Reactive identity assumptions we describe in the book (my relationships, results and/or intellect define my sense of worth, security and value). This often drives behavior that limits their effectiveness. In that sense, Achievers are growing into and are still very much maturing the self-authoring capacities that usher in higher levels of effectiveness. We agree with Bill Torbert: “Our research specifically points to a link between the post-Achiever frames and the manager’s tendency to propose collaborative rather than unilateral action in response to problems” (Torbert, 2004, p. 109).

Research: There is a lot of solid research establishing the various stage models and the ability to measure distinctions between different levels of meaning making. The research on how this relates to leadership effectiveness and business performance, however, is a young and emerging field. Much more research is need to firmly and more conclusively establish how the various stages relate to business metrics, leadership effectiveness and to the leadership literature. The early research is encouraging and shows significant positive correlations. The research we present in this book is consistent with current studies. We hope it contributes to the body of research and calls forth much more research.

On pages 54 and 55 of our book, we present our findings on the correlation between Leadership Effectiveness and Stage of Adult Development (measured by the MAP). The pattern in this data is interesting for a number of reasons. First, there is a strong positive correlation (.65). Second, while we do not call this out in the book, there is no difference in effectiveness scores between Experts (3.5) and Achievers (4). The average scores are so close as to be identical. Third, there is a significant jump in effectiveness scores that happens at post-conventional levels (4.5 and beyond). This pattern is consistent with the research Kegan and Lahey (2009) reported in their book, *Immunity to Change*. On page, 24 they summarize Eigel's research on the relationship between "Individual mental capacity and business effectiveness." In this graphic we see a similar pattern to the results we report. There is a significant and obvious positive trend and some, but not a large, difference in measured effectiveness scores from 3/4 and 4. However, at 4/5 there is a significant jump in scores. This pattern also lines up with Torbert's well-known findings from the longitudinal study of the relationship between CEO action-logics and organizational transformation efforts.

> In all 5 cases where the CEO was found to be at a post-conventional action-logic, the organization transformed in a positive way… these 5 CEO's supported a total of 15 organizational transformations…. Conversely, the 5 cases with pre-Strategist [Diplomat, Expert and Achiever] CEOs yielded no organizational transformations on average. (Torbert, 2004, p. 112)

Various developmental theories have a different number of stages and draw the lines between stages in different places. It is interesting to note that the Torbert research mentioned above, when it was first reported in an article did not include an Individualist Stage. He now includes this stage between Achiever and Strategist (although the names of stages continue to be updated). This suggests that the field (how the levels are defined, where the lines are drawn, and how the various theories and measurement methods relate) is still evolving.

We needed to make a judgment call about where we draw the line between Creative and Reactive in the most business relevant way. We did so in light of our best interpretation of the theory and research, and in light of our application experience. For these reasons we describe mature Creative leadership as post-conventional. We think this is consistent with the research and with the way the literature is describing extraordinary leadership—Authentic, Purposeful, Visionary, Emotionally Intelligent, Self-Aware, Change Catalyst, etc. When we claim on page 55 that the average Leadership Effectiveness score of Creative level leaders is 65th percentile, compared to our norm base, we include all managers in our sample that were assessed on the MAP at or beyond 4.5.

To arrive at the figure that 20% of leaders are fully functioning at Creative or higher, we draw on a weighted average of the sample populations presented in Susanne Cook-Greuter's paper, *Nine Levels of Increasing Embrace in Ego Development*. Here the weighted average percentage of adults at post-conventional stages is 22.8. For the convenience of our reader we round this to 20%. We think this is a good estimate of the percentage of leaders functioning at the mature Creative level or higher.

In our book we do not make all of these theoretical distinctions apparent. Consequently, as Jonathan points out, we describe the work of developing Creative Leadership as the work of becoming more and more self-authoring. We link this to Kegan's model at level 4, Self-Authoring, because this is a very apt description of the primary work at this stage, and of the development from conventional into post-conventional.

Jonathan suggested it would be useful to mention how we derived the five question Leadership Effectiveness scale. All of the dimensions on the Leadership Circle Profile were developed in collaboration with the Industrial Organizational Psychology department at the University of Bowling Green in Bowling Green, Ohio. They developed and provided this scale.

Everything discussed in this response to Jonathan's review, we believe, is a wide-open area for further research. There is more research needed about how the various developmental models and their different methods of measurement relate to one another. More importantly, there is relatively little research on how all this relates to leadership effectiveness, business performance and the practice of developing more effective leadership. Early research is encouraging, but there is a long way to go. As this body of work expands, and we better refine these important distinctions, we expect to be both contributors and learners on this journey.

Our hope in writing this book is that we can help to bring developmental frameworks center stage and best practice in how we go about developing leaders. We further hope that this will stimulate much more research into the relationship between leadership effectiveness, competency and Stage of Development.

We thank Jonathan Reams for his review of *Mastering Leadership*, and for providing us the opportunity to respond.

July 2017 Special Issue Introduction

Issue Editor: Bahman A. K. Shirazi[1]

The focus of this special issue of *Integral Review* is centered on two principle themes. The first theme is integral education, the educational framework that was first developed by Sri Aurobindo and Mother Mirra Alfassa (a.k.a. The Mother) as part of their integral world view. Sri Aurobindo, who was sent to England at age seven to receive a Western education, returned to India in 1893 and dedicated his early work to the cause of liberation of India from the colonial British rule. His ideas on education had significant implications for the educational system of India, which was dominated by the British at the time. A few decades later, as more and more followers and their families joined the Sri Aurobindo Ashram community in Pondicherry, India, The Mother became directly involved with educating the Ashram children and started a school in 1943, which is known today as the Sri Aurobindo International Centre of Education.

In *The Modern Knowledge Academy, Vedantic Education and Integral Education,* Debashish Banerji explores how Sri Aurobindo and the Mother's vision of integral education integrated aspects of ancient Vedantic principles with modern knowledge academy. Banerji starts with the early 20th century discussions on education that took place among key intellectual figures of India about the national system of education and the challenge of reconciliation of traditional epistemologies with Western educational values. Among topics discussed were giving priority to native languages, equal valuation of the sciences and humanities, and intellectual understanding versus inner and intuitive sources of wisdom.

Banerji characterizes the modern knowledge academy, which is rooted in scientific and empirical methodology, as being objective and universal in its outlook, thus deemphasizing subjectivity and the role of individual knowledge. At the same time, he maintains, the universal humanism that emerged was important to individual liberation and equality both in the West and for colonized people in contrast to native pedagogy, since indigenous education in India was often based on a patriarchal and authoritarian model. As Banerji puts it "… the critique of national education cuts both ways – finding principles in the modern knowledge academy to correct biases and prejudices of the past, while also contesting the definitions of epistemology and pedagogy based on indigenous knowledge systems." Banerji argues that in the Vedantic approach to knowledge ontology and epistemology are not separate and that Vedantic epistemology aims at overcoming the subject-object split through intuitive approaches and direct non-dual experiences of the Self. He concludes with a discussion on how Sri Aurobindo reconciles epistemologies of modern knowledge and nativist approaches to knowledge and how it can be implemented in a post-secular global society.

In the next article, *A Complete Integral Education: Five Principal Aspects*, Jeremie Zulaski reviews the five principal aspects of a "complete integral education" envisioned by Sri Aurobindo and The Mother using several of their key writings in this area. After a brief critique of the current educational models, the author provides an outline of integral education and concludes that "a complete integral education contributes a potentially corrective alternative to outmoded orthodox methods that privilege intellectual proficiency over the holistic knowledge potentially present, given authentic engagement of learning communities." Integral education is often referred to as education for the whole person which is typically defined as engaging the mind, body and spirit in recent literature and by certain educational establishments, including CIIS. However, in integral education based on Sri Aurobindo and the Mother's teachings the whole person is defined in terms of five major constituents: the physical/somatic, the vital/affective, mental/cognitive as well as the psychic and the spiritual dimensions. Using the available teachings by Sri Aurobindo and the Mother the author examines each of these areas in some detail.

The next article by Heidi Fraser Hagerman is an empirical study involving the alumni of the East-West Psychology (EWP) Program at CIIS. This program started in the mid-1970s and has gone through a series of changes in its curriculum. In the 1970s it bridged Asian psychologies such as yoga psychology and Buddhist psychology with the emerging Western schools such as Jungian, existential, humanistic, and transpersonal psychologies. Over time, the East-West dimension was expanded to embrace a more global vision by including indigenous and sacred psychologies, contemplative psychology, and more recently areas such as ecopsychology and consciousness studies. Today the educational vision of the EWP program explicitly aspires towards an integral education that honors intellectual excellence as well as the wisdom of the somatic, vital, emotional, imaginal, and spiritual dimensions of the person in order to foster transformative inquiry and learning and to facilitate psychospiritual development.

The article titled *The Value of an Integral Education: A Mixed-Method Study with Alumni of the East-West Psychology Program at the California Institute of Integral Studies* is a unique and original study to engage graduates of the program to explore the relationship between their integral educational experience and their personal and professional development. According to the author, "The findings revealed that their experience and understanding of integral education in EWP is mostly in alignment with the ideals of CIIS; namely, honoring multiple perspectives, the multidimensionality of being, and multiple ways of knowing …" The study also uncovers areas that need further development such as more focus on practical and professional development, further support for students' psychospiritual development, and communication skills to convey the value of an integral education effectively with communities outside of CIIS.

The remaining articles in this issue explore a key aspect of integral education and world view; namely, women's spirituality and integral feminist pedagogies. Alka Arora's article titled *Women's Spirituality at CIIS: Uniting Integral and Feminist Pedagogies* sets the foundations for an educational framework termed integral feminist pedagogy, which is an attempt at uniting the principles and practices of both the integral and feminist traditions. Arora critiques a particular narrow view of integralism that "divorces individuals from their social and political context" and argues for a framework that not only takes into account the unification of mind, body, and spirit, but in addition integrates the social and political context which is the focus of Feminist pedagogy.

This position is in fact resonant with CIIS founders' vision of integration of the personal and psychological dimensions of spiritual practice with social, cultural, and political awareness and transformative action.

The next article by Arisika Razak entitled *The Divine Feminist: A Diversity of Perspectives That Honor Our Mothers' Gardens by Integrating Spirituality and Social Justice* further builds on the theme of integration of spirituality and social justice. Citing a number of key figures in the women's spirituality and related movements, Razak argues that while spirituality has often been separated from feminism, a number of prominent scholars in diverse fields such as Africana and Chicana studies, Indigenous studies, Islamic studies, queer studies and women's spirituality "have all linked empowered roles for women and other oppressed groups to contemporary and historic liberatory spiritual frameworks and culturally specific Indigenous roles for women and other oppressed genders."

Razak defines the contemporary *divine feminist a*s "one who walks the contested borderlands between secular feminisms, philosophy and religious studies, and ethnic/indigenous studies" by integrating "diverse spiritual frameworks elaborated by people of color, liberatory theory and praxis supporting the empowerment of women and other oppressed genders with Euro-American academic perspectives, and contemporary disability and embodiment studies" to develop new forms of activism, scholarship and alliance building.

Monica Mody's article, *The Borderlands Feminine: A Feminist, Decolonial Framework for Re-membering Motherlines in South Asia/Transnational Culture* is an excellent example of the kind of scholarship embraced in the previous two articles. Mody engages Gloria Anzaldúa's "borderlands framework", an alternative new consciousness and "a profoundly relational, integrative onto-epistemological praxis", to empower the marginalized sacred feminine in the context of South Asian motherlines by offering a radical synthesis of spiritual healing with anti-oppression work. She writes:

> [c]reating self-affirming, complex images of female identity, and making revisionist myths—while engaging the self in relation to culture— constitutes a decolonial practice. It enables South Asian women—as the Others of colonial modernity and brahmanical patriarchy—to renew their relation to an episteme of the sacred that liberates their voices, vitality, and authority.

Earlier Banerji argued that the Western "universal humanism … was important to individual liberation and equality both in the West and for colonized people in contrast to native pedagogy since indigenous education in India was often based on a patriarchal and authoritarian model." Mody argues that neither the patriarchal system in India nor the universal humanism of the West would provide the right solutions and offers a post-secular decolonized recovery at the edges of the postcolonial feminist subjectivity through the borderlines framework that "forefronts the grandmothers, the foremothers, and the experiences of women of color on their own terms."

In the final article, Karabi Sen introduces *Chinmoyee* and *Mrinmoyee*, two different ways of looking at divinity in the feminine form in traditional Indian context. Chinmoyee and Mrinmoyee refer to the divine female principle in the context of Hindu philosophy and religion which have often been interpreted by philosophers and common people alike as opposites, much in the same sense that mind and matter have been held as opposite in dualistic philosophies. In the spirit of non-dual philosophy, Sen proposes that the two aspects of the divine feminine, the transcendent and the embodied, are essentially two aspects of the same unified consciousness. Through various philosophical arguments as well as references to some of the current growing-edge work in science, and Sri Aurobindo's views on the stages evolution of life, Sen creates a platform where "the scientist, the philosopher and the saint join hands" to address the questions about our relationships to the whole, our course of actions and our choices behind our actions if we choose a "*conscious foundation* for our vision of harmony with the whole universe upon the discovered unity and link between our body and the rest of the bodies, our life and the rest of the lives, our values and those of the others."

The essays selected for this special issue of Integral Review represent a small cross-section of current integral scholarship at the California Institute of Integral Studies. We are grateful to *Integral Review* for providing another opportunity to share these ideas with the larger community of integral scholars.

The Modern Knowledge Academy, Vedantic Education and Integral Education

Debashish Banerji[1]

Abstract: The early Upanishads provide a model of education which Sri Aurobindo drew on for his system of education, which has been called "integral education." Yet, having himself been educated in some of the canonical institutions of the modern knowledge academy, Sri Aurobindo's views on education did not adhere to a nativist or essentialist interpretation of indigenous knowledge. This article will consider the critique of both modern knowledge as well as of nativist approaches to knowledge acquisition and dissemination implicit in Sri Aurobindo's and the Mother's vision of integral education; and if or how that can be implemented in a post-secular global society.

Key Words: Integral education, Sri Aurobindo, Vedantic Education

The Modern Knowledge Academy

Questions of restructuring higher education, whether to empower indigenous forms of knowledge or a more integral knowledge (whatever that may mean) require foremost, a critical consideration of the disciplinary boundaries of the modern knowledge academy, within which all such considerations are conducted. What are the assumptions of the academy, from where did they come, who/what owns it and/or is owned by it, and what do they allow or disallow from consideration?

Questions such as these were quite naturally of critical importance at the turn of the 19th/20th century in Kolkata, India, where a native Bengali intelligentsia met to discuss the shape of a national education project. Aurobindo Ghose, later Sri Aurobindo, the philosopher-sage of Pondicherry (and one of the seminal influences on CIIS founder Haridas Chaudhuri), and Rabindranath Tagore, the first non-western Nobel awardee for literature, considered by many

Indians as the conscience of the nation, were participants in these discussions. In forwarding their analyses and critiques, they considered the place of language, of whole person education, and of traditional epistemologies in comparison with western education. Many of these debates were conducted around the founding curriculum and pedagogical methods of the National College in Calcutta, which became operational in 1905, with Aurobindo as its first principal. Later, both Tagore and Aurobindo continued to develop the ideas voiced in these meetings, giving a more mature shape to them in their own "ashram" institutions, Shantiniketan and the Sri Aurobindo Ashram respectively.

Both were strongly influenced by Vedantic ideas of epistemology and pedagogy – Tagore put to practice his own creative interpretations of these teachings, while Aurobindo developed what he called "Integral Education" on its basis. Neither, however, rejected the epistemology or pedagogy of the modern knowledge academy, both because such a rejection would be a recipe for marginalization and because there were aspects to the modern knowledge academy that provided salutary corrections to some of the shortcomings of indigenous education. The National College is still operating as one of Kolkata's (and India's) major universities, though to what extent it embodies the critiques and suggestions of the National Education Council, is a debatable question.

Principles of National Education

To summarize the ideas of the Council, especially as voiced by Tagore and Aurobindo, we can group them into four major points:

1. Priority given to native languages as the medium of instruction, with the corollary need to advance translation projects of western knowledge into the Indian vernaculars. This idea, strongly advanced by Tagore, had to do with the acculturation of a never-fully-translatable continuous tradition and its engagement, on its own terms, with modernity.
2. Equal importance given to the Humanities and the Sciences/Technologies. This point was emphasized by Tagore, since what was recommended by some was an emphasis on technical education, as the basis for developing equality in manufacturing and industrial management with the colonizer. Unfortunately, in the early implementation of national education, this emphasis on Engineering became predominant for some time, and the National College, later called Jadavpur University, became known as an Engineering school. Fortunately though, today the university is well known for its Humanities as well.
3. Related to point 2, was the question of the educational habitus. Both Tagore and Aurobindo drew on the Vedantic idea of the ashram or gurukula (guru's family) model of educational habitus, which would allow for informal learning as well whole person pedagogy. The implementation of this aspect was contra-indicated by the modern knowledge academy, and the question of how or if at all it could be implemented, remained unanswered. Later, both Tagore and Aurobindo built ashrams of their own, and conceived of the life of the ashram as a form of "unending education."
4. The privileging of the mind, in the modern knowledge academy, and consequent reduction of knowledge to "intellectual understanding" was sought to be countered by other forms of legitimate knowledge. In Tagore's case, one scholar has called it "a feeling-ordered

rationality;"[2] and in Sri Aurobindo's case, it was a tapping into inner sources of wisdom that Vedantic knowledge wrote about. In this context, Aurobindo (2003) came up with his "three principles of true teaching,"[3] of which the first was that "nothing can be taught" (pp. 384-385).

Critique of Modern Knowledge

Before looking at these suggested revisions in detail, or considering what they drew from Vedantic education or what shape they took in Integral Education, it would benefit us to subject the epistemology and pedagogy of the modern knowledge academy to our own critique, based on sources of understanding which are current. The modern knowledge academy, now a worldwide decentralized universal institution, was born out of the 17th/18th century intellectual revolution known as the European Enlightenment. In brief, as a reaction to the dogmas of the Church, European intellectuals sought an object and method for knowledge production that all humanity could agree on. It is the method here that is more important than the object, since the object could more easily be stated as the totality of knowledge of the cosmos (the "what" of human consideration) and the subject of knowledge, the human being (the "who" of its consideration).

What could be universally agreed upon, if we were to avoid being subject to the rhetoric of invisible epistemic real estate of various unverifiable contentions, was what we could affirm as verifiable empirical knowledge, obtained by the senses (or technical extensions thereof), and operated upon by the rational principles of the mind to arrive at testable hypotheses, inductions and deductions. Thus the scientific method became the ground of modern research and the archiving of the results of this method, in systematic form, became the means of acquisition and furtherance of knowledge. This simply put, is the foundation of the modern knowledge academy.

Knowledge here is not the prerogative of any individual, however intelligent, but a constantly developing archive belonging to all humanity; and dependent on all humanity, yoked with or without consent, as knowledge-workers for its production, distribution and implementation. Individuals here did not count for much, because finite human lives, bounded within a small envelope of space (locality) and time (mortality) could only piece together or handle a small quantum of knowledge, while a decentralized knowledge academy, utilizing large numbers of knowledge workers across space and through history, it was supposed, could eventually arrive at the goal of total knowledge and mastery over all circumstances as a result. The assumption behind this was that, since Nature's laws were cognizable by the human mind, the mind would eventually arrive at the Law or small complex of Laws, which explain everything. One might see this as a displacement of the earlier Greek idea of the Logos or Mind-of-God. Of course, not all Enlightenment philosophers believed in this, but it was a pervasive idea, particularly among Deists, who were very influential in shaping the Enlightenment. Since nature was "reasonable" (i.e. lent itself to Reason), human reason would be able to arrive at a total understanding of nature. This could be seen as a kind of "integral" goal.

[2] See the discussion of Rabindranath Tagore in Esha Niyogi De (2002, p. 42) as quoted in Banerji (2010, p.13).

[3] From "A System of National Education" published in 1910 in the nationalist magazine *Karmayogin*. See Sri Aurobindo (2003, p. 384). Later, in his magnum opus on yoga, he reiterates this idea more fully: "Nothing can be taught to the mind which is not already concealed as potential knowledge in the unfolding soul of the creature" (1999, p. 54).

Modern Knowledge and Humanism

The assumptions of universality in this premise made for some attractive consequences which were tied to the larger Enlightenment project. For one, it rested on and inaugurated a universal humanism. In defining a universal method and a universal scope of knowledge, it simultaneously defined a universal subject which would be the natural instrument for this project – a human being possessed of empirical sensory means and rational logical means of knowledge. This meant that all humans were equal in possessing universally the faculties of sense and logic. This equalization, which helped Europe to emerge from the epistemic dominance of the Church, was in a sense, liberative for colonized peoples as well. It provided them with a principle for claiming equality as human beings, not only in relation to the colonizer but also against dogmas of social inequality instituted and accepted in their own native societies. It also however, stood in contradiction to native pedagogy in this sense, since indigenous education, such as what was conducted in the ashram or *gurukula*, was often based on a severely patriarchal model, where the word of the guru couldn't be questioned. One can see here how the critique of national education cut both ways – finding principles in the modern knowledge academy to correct biases and prejudices of the past, while also contesting the definitions of epistemology and pedagogy based on indigenous knowledge systems.

However, the privileging of Reason as the highest human faculty was an inherent bias, which we can see at work to this day in separating humans in terms of superiority. Moreover, as thinkers like Nietzsche were quick to point out, this noble-seeming knowledge project was entangled with the "power" project of making a "perfect world" (Nietzsche, 2009). In fact, for Nietzsche (and closer to our times, for Nietzschean thinkers such as Michel Foucault), the power motive was primary, driving the quest for knowledge so as to possess and enjoy the world, exploiting those who were disadvantaged in terms of the instruments of knowledge or its application (technology) (Nietzsche, 2009; Foucault, 1984: pp. 76-100). Still, the good that modern applied knowledge has done to our world cannot be overlooked; and the leaders of national education in Kolkata did not wish to overthrow technology only because it was one of the prime instruments of colonialism. The famous debate between Tagore and Gandhi on this issue is a good case in point.[4]

Today, we may articulate the problems with the modern knowledge academy in our own way – first, the "integral" epistemological project of the Enlightenment is faulty in its assumption of piecing together all knowledge through an iterative method. Simply speaking, the whole is greater than its parts and cannot be composed from an addition of its parts. However, so long as we harbor this illusion, even as a general possibility, we will be prey to partial wholes that become ideologies laying claim to all of reality. This is the ground for the universalist stridency of modern religions and political ideologies. Faced with a liberal world which champions knowledge acquisition and application as part of a totalistic drive with the assumption of an absolute rational understanding, religious and political ideologies take on a fundamentalist stance in opposition, staking their own universal claims as having global rights. No claim to integrality based in a mentally comprehensive construction, however compelling and inclusive, can encompass the infinite plurality of the cosmos. There will always be something that will escape the "system;" yet driven by the need to claim integrality, there will always be the attempt to close the doors on inconvenient fractions and force a theoretical ideology on the masses – the essence of fascism. It is an understanding of this danger, that made Martin Heidegger open up the method of "destruction" against metaphysics, later continued by Jacques Derrida in the form of deconstruction and by Michel Foucault, through his archaeological and genealogical critiques.

---

[4] Through the 1920s, Gandhi and Tagore corresponded on a variety of topics including Gandhi's national program of boycott of science and technology in native education as well as universal domestic practice of cotton-spinning (charkha). Tagore resisted both views. Though he was sorely conscious of the dehumanization contingent on privileging science and technology over the humanities, he felt the solution lay in balancing the priorities, not in boycotting science and technology. In fact he sent his son to study Agricultural Engineering at the University of Illinois, Urbana-Champaign, so as to apply its methods for more efficient produce at Shantiniketan (Robinson and Datta, 2007).

The problems of the drive for "power," furthered through technology, are even more obvious. Though claiming the goals of betterment and perfection of human life and worldly circumstances, the motives of power are tainted by the impurities of the human ego, and without addressing this, lead inevitably to possessiveness and exploitation, at the foundation of colonialism and capitalism.

Vedantic Knowledge

For an indigenous basis of knowledge, Sri Aurobindo turned to the Upanishads, India's earliest proto-philosophical wisdom texts. The Upanishads are centrally concerned with knowledge, but they understand this quite differently from the modern definition of knowledge. The question of knowledge is fielded repeatedly in the Upanishads. The most succinct form of this question, raised variously in a number of texts, can be found in the Chandogya Upanishad (VI.1.3) and repeated in the Mundaka Upanishad (I.3): "What is the one thing knowing which all may be known?" Purely based on the question, this sounds almost identical to the Enlightenment's project of finding the unitary root of all explanation. But the difference between the two lies in the fact that for the Enlightenment, this is an epistemological project, not an ontological one; while for Vedanta epistemology is never separated from ontology, and the question is a matter not of shareable content but of a certain experience of reality, one through which all is understood. While a rational epistemology proceeds on the basis of a subject-object split, Vedantic epistemology aims at overcoming the subject-object split through non-dual experience. This is done through an insistent focus of attention on the Brahman, the One Being in all beings. In terms of its knowledge project, another way of putting this is the discovery of true Subjecthood (the Atman or Self), whose self-experience is this objective world, cognized substantially as itself (Brahman) and through its faculties, as qualitative (*vijnana*) and functional (karma) forms of self-knowledge. This Self is the self of all selves and may be approached through "self-enquiry." Interestingly, this realization has also been termed "Enlightenment," in the inverse Orientalist sense with respect to the European Enlightenment.

Comparison of Methods

The method to its attainment is no less systematic and rigorous than the knowledge academy's scientific method. It consists in following a psychological praxis, yoga, guided by a realized teacher (guru) in an intimate habitus *(gurukula, ashrama)* where both formal and informal interactions aid the achievement of the realization. The importance of the lived habitus as the site of pursuit of knowledge cannot be over-emphasized in this approach, since knowledge realization is seen here as an existential preoccupation. Yoga is a vast field of experience in India, aiming to realize a variety of goals through a variety of methods and teachings. Of these, the predominating peculiarity of the Upanishads is to privilege the goal of knowledge. The primary method of the Upanishads can be thought of as the four stages of preparation, reception, contemplation and realization. The clearest articulation of this method comes in the Brihadaranyaka Upanishad (II.iv.5) in the words of the sage Yajnavalkya teaching his wife Maitreyi:

> आत्मा वा अरे द्रष्टव्यः श्रोतव्यो मन्तव्यो निदिध्यासितव्यो मैत्रेयि,
> आत्मनो व अरे दर्शनेन श्रवणेन मत्या विज्ञानेनेदं सर्वं विदितम् ||
> (The Self, my dear Maitreyi, is to be realized – by hearing of it, cogitating on it and entering into intimate contact with it (or intuiting it); By the realization of the Self, my dear, through hearing, cogitation and intimate relation (intuition), all this is known).[5]

It should be noted that this method is directly related to the goal of Vedantic knowledge[6] in the second line. Here, what is to be received (or heard) can be variously construed as: (1) the teaching of the guru;[7] (2) the revelatory (mantric) utterances (*mahavakya*) of the Upanishads; (3) the cognitive and phonetic structure of the Upanishad.[8]

It is also interesting to *note that the term dhyana* (concentration) *is not used for the middle term between shravana* (hearing) and *nidhidhyasana* (identity) Rather *dhyana* is contained in *nidhidhyasana*; it stands for wordless contact by consciousness. This is also intuition, an intimacy with the being. But the middle term is *manana*, which means thinking, cogitation rather than contemplation or intuition. This is a cultural use of thinking as a means to lead to thoughtless contemplation. Storytelling and the performance arts exist to amplify this element of *manana*, thinking about the object of relation. The story of Yajnavalkya and his teaching of Maitreyi is itself such a story attracting our interest and making us think of the characters and their actions. This thinking intensifies the attention on the objective being pursued. From this the object starts becoming real, that is, its presence is sensed in its expressions and attracts us to thoughtless wonder (*adbhuta*), the presence of the infinite in the finite.

Social Benefit of Upanishads

Would this praxis have any social benefit? After all, if there is a noble side to the Enlightenment, this is its central concern – how can we create a perfect world? Though monastic communities of intense practice did not concern themselves with social good, the attention on the One generated its own ethical consciousness. Ethics here was not a goal but a natural consequence of the intimacy with the Infinite One. From the post-Enlightenment point of view, if we made practical reason the guide of our actions, we could call this the application of Knowledge for ethical conduct of life through the intuition of unity (dharma). But that would be putting the cart before the horse.

---

[5] Translation by the author.

[6] What is the one thing knowing which all may be known?

[7] It is possible that this included the initiatory bija mantra; but the Upanishads are ridiculing of blind mantra repetition. However, they privilege the pranava, the syllable Om. So it is possible that something like this was made an occasion to convey the guru’s experience, along with recipes for the cogitation and contemplation of the mantra.

[8] It is surmised that the formally structured Upanishads such as the Mandukya or the Isha are relatively late ones. If this is the case, then we can see this as an example of the evolution of Upanishads.

Modernity can level the following critique on the Vedantic knowledge project, since (and ivory chair intellectuals should never forget) modernity is the normalized global episteme within which any other way of being must adapt and participate. Since post-Enlightenment modernity proceeds through the braided discourses of Knowledge and Power, it can level separate critiques on these lines. In terms of Knowledge, the question of the reality of our common world was subjugated to the question of the self or Subject. A subjective science was created and practiced but it remained isolated in sects and lineages in the form of oral knowledge. This is partly why so little of it exists today. The attention to the subjective subordinated the need to archive and disseminate knowledge. The *acharyas* (spiritual teachers) who wrote Vedanta bhashyas (commentaries) came more than a millennium later and produced new interpretations of the Upanishads based on their intuitions; and it is possible that they incorporated in their lineages some of the ancient oral knowledge pertaining to the practical psychology of the Upanishads. Still, it is certain that much is lost due to material inattention. With this loss of oral (or evanescent) traditions, there is also the loss of the history of knowledge production.

The Power aspect of modernity could level the critique that the ideal of perfecting the world through the application of knowledge was not made a social goal here; and perhaps the most serious charge from the viewpoint of modernity is that of an authoritarian basis to the guru-disciple relationship. Though the first of these critiques could be admitted for certain periods and regions, the second can be contested. In modern times, a perusal of Sri Ramakrishna's *Kathamrita* (Ramakrishna, 1942) would provide a very plausible image of a teacher of the Upanishadic age – someone operating as a peer through unpredictable behavior and teaching through stories, actions and locally relevant jokes. Still, the principle of equality which forms the basis of modern relations would not be in place here, keeping open the door to patriarchal domination in the name of an exalted spiritual status.

Post-Secular Integral Education

Sri Aurobindo's mature hermeneutic analysis of the relation between these two epistemologies was given voice by him in the chapter "Knowledge by Identity and Separative Knowledge" in *The Life Divine* (Sri Aurobindo, 2005, pp. 543-572). Here, he draws attention to the fact that what Vedanta calls Ignorance, modern epistemology designates knowledge. This Vedantic understanding proceeds from a psychological view of an indirect and inferred knowledge being an ignorance, the category of "knowledge" being reserved for direct knowledge, viz. knowledge by being. This is in keeping with the lack of separation between ontology and epistemology in Vedanta. One knows because one identifies with the being of that which one knows. Sri Aurobindo was to call this mode of direct knowing knowledge by identity. Our normal mode of knowing, methodized in the modern academy, in which the evidence of the senses is used by the mind to give us a picture of realty, was designated knowledge by external contact by him, a form of indirect knowledge. While knowledge by identity was held out by Indian wisdom texts and yoga traditions to be a possibility, it was taken as a goal only by those few who made a yoga of knowledge their central preoccupation. For Sri Aurobindo however, it assumed the place of a species goal for taking humanity as a race out of the misery of ignorance into the certitudes of direct knowledge. In fact, he could conceptualize such a goal only under conditions of modernity, based on the ubiquity of the modern knowledge academy, which construes humanity as the universal subject of its methodical systems of knowledge production, archiving, dissemination and pedagogy; and the perfection (by technology) of cosmos and humanity as the universal object of its inquiry.

Modern Knowledge and Invented Realities

A corollary of this is the need of modern knowledge to arrive at a single truth and a single integrated statement of the truth. Indian metaphysics or darshan was not invested in such a goal, since it was subservient to a transformational psychology (yoga). Praxis took precedence over theoria; and theoria existed as techne and poeisis of praxis. This meant that theories were invented based on the goals of yoga; so as to provide efficient conceptual handles for dynamics of practice; and development through states of experience. Such theories born as philosophical aspirations (leading to and validated by ontological experiences) invented the realities they set out to realize, under the metaphysical assumption that conscious being was infinite possibility. Not under much compulsion or aspiration to an exclusive epistemology or a perfect society, multiple yogas, yoga-darshans and realizations of reality co-existed under common and more-or-less-fixed material conditions in India.

It is interesting to note that Michel Foucault and Gilles Deleuze both gravitated towards this inverse (viparit) relation between epistemology and existentialist praxis as a turn from the epistemic hegemony of modern knowledge. Both got there, of course, from Nietzsche (2008) and his definition of the human as a “rope thrown between the beast and the god.”[9] For Foucault (2010) these are his subject-making exertions of internal power, acquired through truth-telling (parrhesia) in the interests of the ideal one has set oneself. This is not a social ideal, but an individuating ideal.[10] Individuating ideals arise from existential questions which form problematic fields. Since existential questions belong to the class of questions common to existential beings, one may presume commonalities yet differences to the questions sought to be answered by different existential beings.

Beyond affirming the critical tradition of the Enlightenment, Foucault does not much discuss the ontological implications for commonalities, which may extend individual praxis to social praxis; he veers in the direction of radical individualism or romanticism, to the point of equating the disciplines of subject-making with artistic creativity (Foucault, 1988, p. 49). Deleuze and Guattari on the other hand, think both of the individual and the social and (micro)-political that mediates between them (Deleuze & Guattari, 1996). Not that Foucault is not political; he is in a way, nothing but political, but his politics are an uncompromising radical anarchism. Deleuze and Guattari are no less radical in their anarchism, but they think the conditions of polis and episteme that can manifest a subjective radical anarchism (Guattari, 1995). Can we find a typology for the practices of subjectivity and intersubjectivity that would help to make this possible? This thinking leads to his theorizing the place of philosophy as one of inventing concepts and in other terms, the project of establishing a field of consistency on the field of immanence (Deleuze & Guattari, 1996).

[9] Nietzsche, Friedrich. (2008). “Zarathustra’s Prologue 4” from *Thus Spake Zarathustra*. Retrieved from: http://www.gutenberg.org/files/1998/1998-h/1998-h.htm#link2H_4_0004

[10] Though not a social ideal per se, Foucault relates this to a social ideal in terms of critique (2010).

The invention of concepts arises from questions which belong to existential beings, and/or the Being of Existence. The solutions sought by the existential beings also apply to the Being of Existence. Hence a bridge may be built between the individual and the universal, through relation of individual beings, forming a collective cosmos-realization.

As observed, this approach, which is similar to premodern Indian metaphysics (darshan), inverts the goals of the Enlightenment, based in faith in the primacy of Rationality (Logos), a displacement of the transcendental Solar Divine. The modern knowledge academy hence comes with the assumption and demand of absolute singularity in terms of cosmos, subject and their relation. The demand of the Enlightenment for a single coherent Law that explains All, and the activation of that Law through technology to create a perfect world, came into contact with the empirical transcendentalism of Indian yoga-darshans at the turn of the 19th/20th century. Sri Aurobindo's yoga darshan follows from this, keeping in front the need for individual freedom and agency, the subjective conditions of anarchism or plural becoming. An absolutism which can have only one description violates the condition of pluralism which it must enable— a cosmos of radical anarchism. Sri Aurobindo posits such an aporetic radically plural singularity as the integral. This is not a co-existence of relatives but a state of being. One can intuit it as a higher dimension of being than ours; naturally one and infinite.

Looked at in the Deleuzian sense, Sri Aurobindo's "invention" of the ontology of the integral proceeds from intuiting the vanishing point of these perspectives. I use the term "invention" in the empirical sense of an existential life-journey in which experiences provide intuitions of immanent ideas, forming problematic fields with sets of virtual solutions. The dogmatic image of thought accepts the collectively operating field of solutions; but creative thought can break this conditioning and arrive at a new plane of solutions, a new dimension of evolution (Deleuze, 1994, pp. 147-167). Its intuiting of an adequate description of the field of solutions is its "invention of concepts," intimately related to a form of praxis leading to a form of experience. It is thus that Sri Aurobindo came to the idea of the aporetic integral as a philosophic concept (darshan) and aiming for it, developed the conditions, and the praxis (yoga) of the integral yoga.

We can see how the ideas of Deleuze (and in implication, Foucault), who saw the power of epistemes binding an age arising from new fields of consistency invented by philosophers (Deleuze & Guattari, 1987, pp. 310-350), can lead to a rethinking of the modern academy. It is even more so in the case of Sri Aurobindo, for whom the academy needs to open to a plurality of subjective praxis-concepts (yoga-darshan) and develop the coherence of this field as a universal archive of information and practice along with grammars using which creativity may "invent" meta-realities. Part of this disciplinary field would be the science of categories, media and mechanisms for archiving and accessing subjective experience. Expansion of capacity along this line would lead closer to a mode of thought and experience belonging to forms of cosmic consciousness.

Intuitive Knowledge Consciousness

For the transition from the state of knowledge by external contact to knowledge by identity, Sri Aurobindo (2005) found the need to develop an intermediate intuitive knowledge consciousness, through the discovery and formation of means of "direct contact" (p. 544). This development of an intuitive consciousness thus became for Sri Aurobindo his postcolonial epistemological project, approached through an inward turn to the intellect and senses, their “purification” (*shuddhi*) and their opening to sources of direct knowledge above or within the human surface consciousness.

In his text on transformational psychology, *The Synthesis of Yoga*, Sri Aurobindo (1999, pp. 799-810) outlines some paths towards the formation of an intuitive mentality. These are related to alternative practices:

a) Achieving a cessation of thought (nirvana) and keeping that blank, in a state of receptivity to near self-evident (nonduality) experience, presented through the subjective appropriation of the senses, which could be called states of objectified intimacy (pp. 802-803).
b) As a variation or degree of a), achieving the ability to refer all questions to a transcendental source and receive its answers without distortion (*shuddhi*, purification) (pp. 805-806). Without a panentheistic intuition of consciousness, the notion of a transcendental, on which this practice rests, could not arise.
c) Once again resting on a panentheistic intuition, the receptivity of a purified (simplified and neutralized, *shuddhi,* and equanimity, *samata*) emotional (heart center, *anahata*) channel to “the immanent Knower/Controller and (universal) Self within” (*jnata purusha*, *antaryamin*, *antaratma*) (pp. 803-805). Sri Aurobindo identifies this immanent intuition with Socrates’(2005) “daemon” (p. 238), the inner leading, that as Plato avers, Socrates never disobeyed.
d) The use of thought to go beyond thought into realms of intuition (pp. 806-807). Though Sri Aurobindo does not provide examples for this, this entire area should be of interest to pedagogy in the modern knowledge academy, since it does not violate the latter’s requirement of logical argument.

Examples of Intuitive Mentality in the Academy

Since these are forms of intuitive mentality, we may look for examples within the modern academy, particularly in disciplines which make the most stringent applied use of thought, such as mathematics or the physical or life sciences. The first method requires sustained conscious discipline, such as of a meditation system like raja yoga to arrive at a thoughtless state and spontaneous examples of pure receptivity in a silent mind are not to be expected in normal human mental functioning, at however high a pitch of intelligence or imagination. Still something resembling this operation of intuition, coming unbidden to a genius, can be seen in the case of Srinivasa Ramanujan (1887–1920), who claimed he received “thoughts of God” that were given to him by the goddess Namagiri Lakshmi of Namakkal in dream, through directly revealed mathematical formulae (Ono and Aczel, 2016, p.67). There is little of a method possible in this category, except for the preparation of mental passivity and receptivity, which, indeed, is more specifically addressed by practice b.

An example of a researcher in the sciences experiencing intuition of the kind related to practice b is Friedrich August Kekule (1829-1896), the German Chemist, who discovered the ring structure for Benzene. Having grappled with his data for a long time, Kekule came to an impasse. In his words:

> I was sitting writing on my textbook, but the work did not progress; my thoughts were elsewhere. I turned my chair to the fire and dozed. Again the atoms were jumbling before my eyes. This time the smaller groups kept modestly in the background. My mental eye, rendered more acute by the repeated visions of the kind, could now distinguish larger structures of manifold conformation; long rows sometimes more closely fitted together all twining and twisting in snake-like motion. But look! What was that? One of the snakes had seized hold of its own tail, and the form whirled mockingly before my eyes. As if by a flash of lightning I awoke.... (Kekule as quoted in Roberts, 1989, pp. 75-81)

Here a method can be distinguished. One may gather all the information one can on the subject and offer it up to another level of understanding or knowledge not accessible normally (and hence, transcendental), and wait for the answer to come through states of dream, imagination or other form of revelation.

An example from the life sciences that can be adduced for practice c is the discovery of "jumping genes," DNA sequences that transpose themselves to other positions in a chromosome without external agency. McClintock, in her biography, speaks of studying maize cells under a microscope and experiencing non-verbal communication and identity with the elements of the cells, leading to her discovery of the very unusual behavior of these genes. She attributes her experience to "a feeling for the organism," a phrase her biographer, Evelyn Fox Keller (1984) used for the title of her biography. In her press statement for the Nobel Prize in Physiology/Medicine awarded to her for this in 1983, McClintock noted: "It might seem unfair to reward a person for having so much pleasure, over the years, asking the maize plant to solve specific problems and then watching its responses" (McGrayne, 2001, pp. 144-174). This demonstrates the affective dimension of knowledge, which we usually associate with the humanities, operating here in the rigorous domain of science.

An example of method can be seen in the case of Albert Einstein, who made frequent use of what he called "thought experiments." These were attempts to think of boundary conditions of experience and arrive at hypotheses, which could be worked out theoretically through mathematical physics and practically through empirical observation or experiment. Here we find the use of thought to stretch its capacity to intuit what lies at or beyond the borders of sensible knowledge.

Subjugated Knowledges – Affective, Volitional and Physical Intuition

In Sri Aurobindo's model of human consciousness, however, the arrival at a mental understanding through intuition is a partial and instrumental use of intuition. Even as instrumental use, there are forms of intuition relating to other modes of consciousness through which we simultaneously experience reality, but which are given less importance (subjugated knowledges) under the post-Enlightenment privileging of mind in modernity. These other independent modes of consciousness include the physical, the affective and the volitional (Sri Aurobindo, 1999, p. 804).[11] In practice d for building an intuitive mentality, we came across a use of the affective intuition to achieve the goals of the mental understanding. But affective intuition has its own ontological domain, effects and functions. The romantic impulse in poetry or other creative arts, connecting the individual through affective intensity to an intimacy in being with the object of consideration, is identical at its root with the sense of numinous intimacy with all things experienced by mystics in their love-affair with the cosmic Being. The method in developing this intuition would be an affective openness to the cosmos as a conscious Being and all its beings as instances of its expression.

---

[11] It is possible to infer different forms of intuition pertaining to each of the chakras in the sevenfold system of Tantra in Sri Aurobindo's later writings, but in general he worked with these four kinds of consciousness each with their own intuition.

In the west, examples of the above may be found among the romantic poets, such as William Wordsworth or William Blake, who gave voice to the cosmic expansion of space and time in such experience in his first four lines of the poem, Auguries of Innocence:

> To see a World in a Grain of Sand
> And a Heaven in a Wild Flower,
> Hold Infinity in the palm of your hand
> And Eternity in an hour.[12]

And from India, Rabindranath Tagore provides a good example of affective intuition in his nature mysticism (Gitanjali, poem 97):

> WHEN MY play was with thee I never questioned who thou wert. I knew nor shyness nor fear, my life was boisterous.
> In the early morning thou wouldst call me from my sleep like my own comrade and lead me running from glade to glade.
> On those days I never cared to know the meaning of songs thou sangest to me. Only my voice took up the tunes, and my heart danced in their cadence.
> Now, when the playtime is over, what is this sudden sight that is come upon me? The world with eyes bent upon thy feet stands in awe with all its silent stars.[13]

This ontological intuition of the cosmic being in each of its manifestations and in itself, arises here from affect. However, affective intuition is not only ontological or epistemological. It may be eminently practical as in the instances of the "daemon" of Socrates referred to by Sri Aurobindo (2005, p. 238). Here, the affect is at work in the trust one has towards the immanent Guide, to whom one can surrender unconditionally (*samarpan*) and receive the direct command (*adesha, shruti*) or revelation (*darshan*) on what is to be done (*kartavyam karma*). It is this kind of knowledge of guidance in action that Aurobindo had sought when he approached Vishnu Bhaskar Lele as a yoga guru in 1908. Lele's meditation instruction gave him the silence of the mind which I have referred to above as the foundation for method a for building an intuitive mentality. But it also gave him the experience of total surrender to Narayana/Krishna as the Supreme Divine and his inner Guide, from whom he received directions from that time.

The knowledge of what is to be done, however, is not merely a directive or revelation received by the inner senses and carried out by the will and body. The energetic (vital) constitution has its own seeking for the direct control of its impulsions by a higher Will, which it can translate to action, with or without (or sometimes before) the mind's understanding or sanction. This is the volitional intuition, which operates as a "hunch" evidencing a relation of will or power between all beings and things. If affective intuition rests on a relation between the individual and other beings or the cosmic/immanent Being, volitional intuition rests on a relation in becoming with all becomings and a participation in the cosmic Becoming. As an energetic intuition, it provides impulsion to the will, both in mind and body and is also dependent on the immanence of the integral principle of Becoming (*Kali, Iccha Shakti*) in all beings.

[13] http://tagoreweb.in/render/ShowContent.aspx?ct=Verses&bi=72EE92F5-BE50-40B7-EE6E-0F7410664DA3&ti=72EE92F5-BE50-4B67-0E6E-0F7410664DA3 (last accessed 12/02/2016)

This is the kind of intuition drawn on by Henri Bergson in his invitation to experience reality as a vitalism of Becoming. Gilles Deleuze, in explicating Bergson's apprehension of vitalism, sees it as a philosophical method, and had titled his Book on Bergson in these terms – *Bergsonism: Intuition as Method* (Deleuze, 1990). In this sense, vitalism is not primarily an energetic intuition, but becomes a philosophical one of methodically divesting oneself from a spatial perception and analysis of "given" objects (actuality) to an apprehension of their pre-individual basis and the dynamic relations of forces that constitute their problematic field (virtuality). An apprehension of this kind is also inventive of the reality it intuits, since it perceives the problem in a certain way which allows for certain outcomes not yet manifest.

Finally, the direct knowledge of the body, evidenced in acts of physical skill belongs to the operation of physical intuition. Picking up accurately without measurement, a predetermined weight in one's hand is an example Sri Aurobindo gives of a translation of mental requirements to the physical intuition. A good example related to the modern academy is the Japanese American architect, George Nakashima, who worked towards marking pieces of lumber directly with his hands, and without using any measuring rule (Nakashima, 2012).

Integration of Intuition

Development of intermediate knowledge resources in the form of varied modes of intuition need, at the same time, to be integrated through the development of the ability to move at will between these forms of consciousness, and enhance the sense of the combined working of all these forms as different instruments of individual knowledge. With the increasing normalization of such intuitive subjective properties, the deeper sense of personhood, belonging to what Sri Aurobindo (2005) calls "the psychic being" (p. 926) will increasingly come to the fore as the integral experiencing subject.

Clearly, all these forms of intuition, however methodically developed, need to be tested and supplemented through standard intellectual measures, until they produce repeatable results. To introduce such goals and methods in the academy, even as experimental possibilities of subjective knowledge, would require existential integration of informal opportunities as part of the learning habitus. This can be implemented officially through residential learning in intentional communities, or through collective cohort formation, flipped learning and/or mentorship models. Agency for learning/realization must be accepted by the student, so that the teacher is minimally involved in conveying content, rather his/her role is to facilitate learning through suggesting resources and methods, generating problems through dialog and leading by example. The learning environment cannot operate on the unequal basis of a gurukula; and egalitarian settings must be developed for the promotion of these forms of intuition. Validation methods and archives of subjective experience/knowledge need to be developed phenomenologically within the learning environment, towards the constitution of an additional domain of subjective science in the academy.

A Complete Integral Education: Five Principal Aspects

Jeremie Zulaski[1]

Abstract: This article reviews the five principal aspects of a "complete integral education" envisioned by Sri Aurobindo and Mother Mirra Alfassa and elucidated in their writings. This innovative, learner-centered pedagogy encourages holistic development through acknowledgment and cultivation of the five dimensions of a human being—the physical, the vital, the mental, the psychic, and the spiritual. The article suggests that a complete integral education contributes a potentially corrective alternative to outmoded orthodox methods that privilege intellectual proficiency over the holistic knowledge potentially present, given authentic engagement of learning communities.

Keywords: Higher education, holistic education, integral education, Mother Mirra Alfassa, Sri Aurobindo.

Introduction

Beginning in the early decades of the twentieth-century, the primary founders of the *integral yoga* tradition, Sri Aurobindo (Aurobindo Ghose, 1872-1950) and his spiritual co-partner The Mother (Mirra Alfassa, 1878-1973) offered a visionary and holistic approach to the lived experience. This approach focuses on a progressive advancement of self-realization, recognizing the individual nature, multi-dimensionality, and interrelatedness of human beings. In corresponding these ideals with teaching and learning, they proposed innovative guidelines toward the formulation of a unique branch of whole-person centered progressive education, placing great emphasis on individual, global, and spiritual worldviews that had been and remain largely absent in Western education.

The whole-person perspective at integral education's core reflects an evolving and expanding awareness toward the complexities and fullness of our own human composition and experience. Integral education contributes a methodical yet adaptive pedagogical framework and competently holds the potential for the development of other subsequent alternative models—such as experiential and transformative learning as well as critical, engaged, liberatory and radical perspectives—and inherently applies embodied, contemplative, and creative modalities throughout praxis. I will be maintaining use of the term "Integralists" (Ryan, 2005) as it pertains to these founders, whose development of an integral or "complete" yoga laid the foundation for

---

their theories on whole-person education. Transferring an integrative worldview into a pragmatic discipline such as education and determining how to implement these perspectives into classroom environments will benefit from an overview of some key tenets of the Integralists' writings specific to their theories on pedagogy. The purpose of this paper is to introduce and discuss the five principal aspects of the whole-person learner identified by Sri Aurobindo and the Mother. These aspects are interrelated and are intended to be simultaneously honed throughout learner development.

This paper will illustrate that integral education is comprehensive and innovative, establishing guidelines that warrant consideration as a distinct, progressive, and potentially corrective pedagogical model. This is relevant given that over the last few decades, substantive concern has been raised about the overall efficacy, value, and purpose of higher education in the United States. In examining the need for reform, a growing body of educators have begun to concede that on the whole institutions "have stressed the highly instrumental form of learning to the exclusion of personal reflection and integration" (Barbezat & Bush, 2014, p. 4). Beginning early in classroom environments, concentration on achieving "successful" outcomes often comes at the expense of "holistic engagement" whereby learners would begin to engage in creative processes, intuitive inquiry, and self-reflectivity. These deficiencies likely contribute to the accruing evidence that illustrates many students enter college "with attitudes, norms, values, and behaviors that are often at odds with academic commitment" (Arum & Roksa, 2011, p. 3). In higher education, value is placed on critical, analytical, and logical thinking, without guiding students in the use of subjective and experiential measures for determining the meaningfulness and relatedness of content. These systematic conditions contribute to poor preparation, lack of commitment, and inadequate knowledge of chosen areas of occupational interest on behalf of students. Additionally, campus cultures are frequently focused on peer development within extracurricular and social activities instead of academic endeavors. Not surprisingly, the industry has been brought under scrutiny from legislators, parents, and policy makers along with classroom educators (Arum & Roksa, 2011; Barbezat & Bush, 2014). The integral model may prove beneficial during what appears a necessary revisioning of a Western educational system that principally utilizes increasingly outmoded practices.

Given the focus of this article, I will not be addressing key contributions by Haridas Chaudhuri (1913-1975), who in significant ways expanded, updated, and implemented integral education with an emphasis on higher education in the West. Readers interested in an introduction to Chaudhuri's developments in this area should refer to his writings on education (Chaudhuri, 1974) and integral consciousness (Chaudhuri, 1977 & 1979) as listed in the references section. Additionally, other prominent perspectives embracing the term "integral" will not be addressed herein. While acknowledging sizable contributions to an integral worldview through models of human consciousness as well as syntheses of major disciplines of human knowledge from Jean Gebser (1905-1973) and Ken Wilber (1949-), in my view it should not be overlooked that the methodology and definitions unfolding from integral yoga and its expanded perspective on whole-personhood precedes these other perspectives by decades. Kaslev (2007) goes so far as to posit that later perspectives and formulations employing the term integral "came about as the result of the former (and not just through superficial and intellectual influence)" (para. 22). Lastly, the integral yoga and subsequent developments in education of Sri Aurobindo and the Mother have no direct connection to Sri Swami Satchidananda, the spiritual teacher who registered the name "Integral Yoga" in the late 1960's before launching the first "Integral Yoga Institute" in 1970.

Potential audiences of interest may include current and future students, teachers, curriculum and policy designers, and other administrators in the discipline as well as those interested in human development and potential. Sources primarily consulted in this paper are three booklets of compiled writings from Sri Aurobindo and the Mother entitled, *Education: General Principles, Education: Teaching* and *Education: Learning,* which were all published in 1972.

Integral Education and the Unique Purpose of the Whole Person

The model of integral education offered by Sri Aurobindo and the Mother emerges from a spiritual worldview and proposes a comprehensive whole-person approach**,** defining the value and purpose of learning as being central to self-fulfillment. An educational process is essential for accompanying learners toward identifying and coming into relation with their *Psychic Being*. The Psychic Being is the embodied divine principle, "the earthly half of the eternal, evolving part of the human soul, manifest as light in the heart of each person" (Julich, 2013. p. 83), serving to guide one toward their highest personal ideals and evolution as a human being. It is this evolutionary aspect of the soul that influences one in realizing one's *svabhāva*, or the unique and intrinsic state of being, and actualizing the *svadharma*, that individual's own path of purpose, individual life-calling, and true self-unfoldment. These two concepts are key components within the integral vision of pedagogy, providing an expansive scope for orientation, interpretation, and adaptation by educators while valuing personal as well as communal enrichment and fulfillment.

Five Principal Aspects

In *Education: General Principles* (Ghose, A. & Alfassa, M., 1972 a), the Mother informs us that in order to be "complete", an integral education must possess "five principal aspects relating to the five principal activities of the human being: the physical, the vital, the mental, the psychic, and the spiritual" (p. 8). These innate human attributes are acknowledged as being fundamentally holistic, humanistic, and divine and must all be addressed to achieve a *complete integral education.* Being interrelated, they require cultivation individually and collectively. The remainder of this section elaborates on and briefly discusses each of these principles in the order cited above.

Education of the physical. In traditional education, a near exclusive prominence has been attributed to the cognitive and intellectual models of acquiring knowledge; "essentially, an exclusively or eminently intellectual approach perpetuates the 'cognicentrism' of mainstream Western education in its assumption that the mind's cognitive capabilities are or should be the paramount masters and players of learning and inquiry" (Ferrer, Albareda, & Romero, 2005, p. 311). As such, recognition and inclusion of the physical body in the learning process, in higher education in particular, has been considered at best recreational and ancillary; playground recess and competitive sports are familiar activities disconnected from learning outcomes present in the classroom. There is a miscomprehension of the essential co-relationship between the mind and body as mutually important vehicles in both acquiring and generating valid knowledge. Thus, the cultivation of a mind-body interrelationship within a whole-person framework is often neglected.

Integral education honors and engages the learner's unique human body and its higher potentials. The Mother dismisses an embodied education as a secondary or recreational consideration for learning in her admission that the physical aspect of learning needs to be rigorous and methodical in its undertaking. She elaborates that an education of one's physical body is comprised of three principal aspects, "(1) control and discipline of functions, (2) a total, methodical and harmonious development of all parts and movements of the body and (3) rectification of defects and deformities…" (Ghose, A. & Alfassa, M., 1972 a, p. 10). Implementing a consistent and individualized pedagogical approach in response to the recognition that the body is habit-forming in its nature is advocated. According to the Mother, these habits "should be controlled and disciplined yet…supple enough to adapt themselves to the circumstances and the needs of the growth and development of the being" (Ghose, A. & Alfassa, M., 1972 a, p. 9). Sensitivity to circumstance and creative adaptation is thereby advised for proper development of the physical aspect.

The physical aspect is a necessary and foundational component of the integral model. Somatic, kinesthetic, expressive arts, martial arts, athletics, dance, and other embodied practices can aid in developing realms of knowledge informed by our unique physical intelligences. These intelligences play an essential role in student health, well-being, and creativity which ultimately influence self-efficacy.

Education of the vital. The following aspect is that of the vital, which seems to share some common characteristics with the emotional, instinctual, or libidinal operative processes. The Mother defines one's "vital being" as the "set of impulses and desires, of enthusiasm and violence, of dynamic energy and desperate depression, of passions and revolts" (Ghose, A. & Alfassa, M., 1972a, p. 10). It is divided into two distinctive yet equally important categories, varying in both goal and process. The first categorical distinction invites one "to develop and utilize the sense organs", while the second requests the learner "to become conscious and gradually become master of one's character and in the end to achieve its transformation" (Ghose, A. & Alfassa, M., 1972a, p. 11). These two categories—sense organs, through which one receives information from the environment, and reflective self-examination, whereby one considers one's reactions, thoughts, and experiences from an internal perspective—provide learners with a spectrum of sensorial, perceptual, and contemplative information. This allows for a more comprehensive, holistic ontology from which to engage in the lived experience. These categories will be revisited and further elaborated on when we discuss the education of the mind.

A vital education is intended to encourage consideration, self-reflection and an honest evaluation of one's internal, energetic, and emotional processes. To provide one example, Mother advises entering "into the heart of your grief: you will find there the light, the truth, the force and the joy which the pain hides" (Ghose, A. & Alfassa, M., 1972b, p. 4). Prescriptions for how to engage with the vital aspect are meaningful, since she interprets that "with the collaboration of the vital, no realization seems impossible, no transformation impracticable" (Ghose, A. & Alfassa, M., 1972a, p. 10). This aspect is considered as that dimension most challenging to entrain, necessitating sincerity, patience, discipline, endurance, and volition. The requisite perseverance and intention are necessary to enter into one's personal vulnerabilities and encounter the transformative authenticity to which they are connected; this is the all-important practice of coming to truly know oneself.

Vital impulses in the form of desires are energies that greatly contribute to shaping and establishing behavior patterns which in turn may eventually solidify into bodily habits. Being so, the Mother advocates for beginning the training of this aspect in the learning process as soon as developmentally possible to best avoid the generation of lesser habits. She elaborates that one is to then "acquire control over one's movements so that one may achieve perfect mastery and transformation of all the elements that have to be transformed. Now, all will depend upon the ideal which the effort for mastery and transformation seeks to achieve" (Ghose, A. & Alfassa, M., 1972 a, p. 11). Thus, in developing sufficient knowledge of the relationship between vital processes, bodily responses and behaviors, and mental reflectivity, one achieves a fuller capacity for alleviating deficiencies. This capacity is aided and enhanced by the observance or formulation of ideal ways of being.

As mentioned in the introduction, a concern with the development of the Psychic Being as the inner guide on one's path to realizing their personal ideal is a central component of an integral approach to educating, to drawing out learners' highest ideals. Having addressed that the vital dimension interrelates with and reinforces one's physical aspect, I will now consider how these two aspects become necessary for the training of the mind.

Education of the mind. A range of cognitive faculties are detailed in regard to an education of the mind in integral education. These include our instruments for attaining knowledge (here being interpreted more broadly than mental, cognitive, or intellectual attainments), memory, progression from object-based to abstract-concept relations, gestalt, contemplation, inspiration, intuition, and imagination. Sri Aurobindo contributes a considerable and ordered series of insights on these faculties. He declares that the first consideration for the teacher should be to interest the learner in "life, work and knowledge", instructing in such a way that will be simple and organic, while effectively examining our "instruments of knowledge" (Ghose, A. & Alfassa, M., 1972a, p. 7). This study of instrumentation is undertaken to assist the student in his or her mental development, "to give him mastery of the medium" (Ghose, A. & Alfassa, M., 1972c, p. 4). As a component of this medium, Aurobindo advises that exceptional training be afforded to memory and that early developmental sharpening of the mental faculties should begin with the observation, comparison and classification of objects, before gradually transitioning to more abstract words, concepts and ideas. This transition toward abstraction naturally entails advancement of the imagination.

Sri Aurobindo is explicit in classifying the imagination as that aspect which is—in addition to self-generating mental imagery and thought-forms—able to acknowledge and admire those emotive and spiritual resonances of existence. He imparts that "Imagination…may be divided into three functions, the forming of mental images, the power of creating thoughts, images and imitations or new combinations of existing thoughts and images, [and] the appreciation of the soul in things…the emotion and spiritual life that pervades the world" (Ghose, A. & Alfassa, M., 1972c, p. 16). He affirms that honing imagination is as crucially important for mental development as guiding the physical senses and comparative analytical faculties. Overall, Sri Aurobindo provides a thorough introduction to how the student may skillfully perceive, classify, and recall the world around him or her, how this pertains to his or her personal understanding, how this comes to inform his or her internal mental generative processes, and finally, what it may reveal about his or her individual purpose, communal responsibility, and spiritual orientation.

Equally as thorough in her written comments on the mental aspect, the Mother lays out five principal phases detailing a comprehensive approach to refinement of the mind that impart a willful, yogic approach to its education. The five phases she identifies include:

1. Development of the power of concentration, the capacity of attention.
2. Development of the capacities of expansion, wideness, complexity and richness.
3. Organisation of ideas around a central idea or a higher ideal or a supremely luminous idea that will serve as a guide in life.
4. Thought control, rejection of undesirable thoughts so that one may, in the end, think only what one wants and when one wants.
5. Development of mental silence, perfect calm and a more and more total receptivity to inspirations coming from the higher regions of the being. (Ghose, A. & Alfassa, M., 1972a, p. 12)

Despite the above division of phases, the Mother advocates that the goal is a more fully realized overall comprehension. She states that students should endeavor to “understand instead of learning” (Ghose, A. & Alfassa, M., 1972b, p. 7) and discloses that “reason is not the supreme capacity of men, one has to go beyond it” (Ghose, A. & Alfassa, M., 1972b, p. 18) before offering some insights as to how to transcend our reasoning capacities. She submits that through ample development of concentration, the compulsion to think actively is not appropriate in all instances since mental “vibration” can be made to cease and an “almost total silence [is] secured. In this silence one can open gradually to the higher mental regions and learn to record the inspirations that come from there” (Ghose, A. & Alfassa, M., 1972b, p. 11). She further advises that gaining time for effectively completing tasks through developing concentration correlates to one’s will or volition; when this force is added to one’s concentration or focused attention, they possess the recipe for genius, which she determines is an irresistible agency.

In addition to gaining time via concentration and recording inspirations originating in mental stillness, the Mother advocated students learn about history—consequential events in time that have already occurred—as a way to frame the present and begin cultivating the intuitive faculty in preparation “to live for the future” (Ghose, A. & Alfassa, M., 1972c, p. 2); it is in and for the future that learners will make their greatest contributions. The following aspect begins to deal even more directly, deeply, and personally with that future, and by what means the Integralists’ educational model informs it.

Education of the psychic. Albeit more concise than the other aspects outlined prior, the Mother’s written comments on the psychic education provide novel and profound considerations for educators. Revealed in these comments are some insights into the Psychic Being and those related areas of Self and path. She presents a refreshing and progressive view in postulating that “with psychic education we come to the problem of the true motive of life, the reason of our existence on earth…the consecration of the individual to his eternal principle” (Ghose, A. & Alfassa, M., 1972a, p. 13). Integral education emphasizes comprehension of and concern with a personal and unique contribution that is inherent in each individual. This is an individual's *svadharma*, introduced earlier.

Accordingly, the Mother also refers to the *svabhāva* by clarifying that "it is through the psychic presence that the truth of an individual being comes into contact with him and the circumstances of his life" (Ghose, A. & Alfassa, M., 1972a, p. 13). She determines that to presence the psychic in one's life, it is contingent upon him or her to eradicate selfishness and beyond this, in progressing toward a spiritual way of life, one must become truly selfless. This focus on a spiritual way of being comprises the final principle of a complete integral education.

Education of the spirit. The spiritual aspect in integral education is designated as being of the utmost importance. Sri Aurobindo states that one's "highest object, [is] the awakening and development of his spiritual being" (Ghose, A. & Alfassa, M., 1972a, p. 3). One way in which this awakening is nurtured is through the educational process, which aims to allow one's spirit eventual full facilitation of his or her mature and multi-faceted self. In the literature, the Mother distinguishes the principal of spiritual education as "an education which gives more importance to the growth of the spirit than to any religious or moral teaching or to the material so-called knowledge" (Ghose, A. & Alfassa, M., 1972a, p. 3). Furthermore, she determines the highest aim of education is "the manifestation of Truth…[to] make matter ready to manifest the Spirit" (Ghose, A. & Alfassa, M., 1972a, p. 5).

The development and advancement of the learner's material embodiment is a necessary component for inviting the spirit into full participation, which is the intended result and encouraged outcome for student learners as they proceed to enter into society-at-large. According to the Mother, a fully realized integral education should endeavor to position the "legitimate authority of the Spirit over a matter fully developed and utilized" (Ghose, A. & Alfassa, M., 1972a, p. 4). This level of participation and realization is deeply interrelated with each individual student's conscience—that inner orientation that provides guidance and morally positions one in their life.

As an educator, assisting students with identifying and coming into relation with their true self-guidance is not a matter of conveying concepts to the mind alone. The Mother states that "there is only one true guide, the inner guide, who does not pass through the mental consciousness" (Ghose, A. & Alfassa, M., 1972c, p. 22). Aurobindo clarifies that at the outset, the approach to offering moral guidance should be to "suggest and invite, not command or impose. The best method of suggestion is by personal example, daily converse and the books read from day to day" (Ghose, A. & Alfassa, M., 1972a, p. 20). The few instances provided begin to illuminate behaviors that are appropriate to influence and shape the character of the student so that they may find their own path in alignment with a personal inner truth arrived at in the course of their learning and development.

From Aurobindo's perspective, each person is ultimately imbued with his or her own individual and unique path and purpose. For integral educators, placing impositions or mandates on the individual student is ineffective and potentially harmful. According to Sri Aurobindo, "to force the [individual] nature to abandon its own dharma is to do permanent harm…" (Ghose, A. & Alfassa, M., 1972a, p. 18). The role of a complete integral education is bringing this purpose to light; as per Aurobindo, "the task is to find it, develop it and use it. The chief aim of education should be to help the growing soul to draw out that in itself which is best and make it perfect for a noble use" (Ghose, A. & Alfassa, M., 1972a, p. 18). To be in alignment with an education complete in the five principles then, Mother states that teachers should assist students in coming to greater self-understanding by guiding them to "know themselves and choose their own destiny, the way they want to follow" (Ghose, A. & Alfassa, M., 1972c, p. 1). To know oneself essentially means, according to the Mother, "to know the motives of one's actions and reactions…To master oneself means to do what one has decided to do, to do nothing but that, not to listen to or follow impulses, desires or fancies" (Ghose, A. & Alfassa, M., 1972c, p. 1). She advises on the appropriate approach to taking steps toward this self-mastery and states in regard to this determination that "if you decide to do something…in life, you must do it honestly, with discipline, regularity and method" (Ghose, A. & Alfassa, M., 1972b, p. 21).

The personal destiny which is to be undertaken by each student can be informed and inspired by a divine agency. This agency is acknowledged as one of the primary five principles of a complete integral education, correlating to the spiritual dimension of human life.

Supramental Education

In the integral yogic tradition, the Supreme evolutionary consciousness of creation is known as the *Supermind,* which Aurobindo has also referred to as *supramental consciousness* or *truth consciousness*. It may be conceived of as an integrated truth-consciousness (or gnosis) and possessing an unlimited transformative power that humanity and all of life has the potential to access. According to Sri Aurobindo: "The supramental consciousness is not a fixed quantity but a power which passes to higher and higher levels of possibility until it reaches supreme consummations of spiritual existence" (Ghose, 1989, p. 539).

This pure plane of consciousness is identified as a concept that will manifest in the field of education, aiding in the advancement of all living beings. The Mother states that the Supramental agency is "the true solution of the problem of suffering" and applies through it reconsiders ignorance, suffering and even death as components of "a transformation, a total transfiguration of matter brought about by the logical continuation of Nature's ascending march in her progress toward perfection" (Ghose, A. & Alfassa, M., 1972a, p. 16). This evolutionary thrust of the Supermind emanates as a transcendent phenomenon, progressively infusing both consciousness and material substance with divine creative potential, and it is determined to thereby usher forth "a new species…a new force, a new consciousness and a new power. Then will begin also a new education which can be called the supramental education…" (Ghose, A. & Alfassa, M., 1972a, p. 16).

Considering that all life is undergoing transition in the evolutionary continuum, an integral worldview provides learners with an awareness that informs that search for individual destiny; a complete integral education is in congruence with this search. The Mother clarifies, "If you want to understand the true reason why you are here, you must remember that our aim is to become as perfect an instrument as possible expressing the Divine will in the world" (Ghose, A. & Alfassa, M., 1972b, p. 1). In this way, one allows oneself to receive new evolutionary creative energies so as to participate in their manifestation on all levels of existence, through one's whole being. The perfection of this individual being is the true purpose of engaging in a meaningful and comprehensive integral education, since according to Mother, "when you want your physical being to be a perfect instrument for manifesting the supramental consciousness, you must then cultivate it, shape it, refine it, add to it what it lacks, perfect what it already possesses" (Ghose, A. & Alfassa, M., 1972b, p. 1). Sri Aurobindo and the Mother affirm that since we are always in the presence of and derived from the Supreme, all of our actions should be conducted as a reflection and offering to this principle. Aurobindo imparts that "one must keep constantly in mind…that you are a representative of the Supreme Knowledge, the Supreme Truth, the Supreme Law and you must apply it in the most honest way you are capable of…" (Ghose, A. & Alfassa, M., 1972c, p. 10).

That each and every person is an instrumental representative of the Supreme generative force with potential to undergo total self-transformation and contribute to and participate in the transfiguration of all life and matter is a penetrating affirmation. The gravity of this perspective places a sobering responsibility on those educators choosing to be aligned with or informed by this worldview and by the pedagogical approach effected from it.

Conclusion

Sri Aurobindo and Mother Mirra Alfassa recognized the breadth and depth of whole-personhood as a fundamental expression in alliance with tenets from a venerable metaphysical philosophy. Out of their modern formulation arose a comprehensive educational model placing priority on each learner's unique make-up and purpose as it unfolds during self-fulfillment. The alignment and interrelationship between the five principal aspects conceptualized in both frameworks honors personal reflection and integration, as well as adherence to methodology, process, and self-awareness.

Educational communities are rightly questioning the efficacy of reductionist and cognicentric approaches exemplified in traditional pedagogies. These conventional biases begin in early education and remain prevalent on college and university campuses, ultimately inhibiting student engagement. The "complete integral education" as outlined by the "Integralists" precedes other correlative contributions and provides a thorough foundation for advancing alternative methods in education.

Integral education places holistic learner development at the forefront while assisting in self-definitions of personal purpose in accordance with values and ethics enveloped in a sacred, yet inclusive, worldview. This worldview acknowledges both an individually unique and collectively interrelated wholeness, offering a much-needed alternative to antiquated educational paradigms that privilege intellectual proficiency over whole-person wisdom. Even if educators reject a sacred perspective and do not wish to consider learners' uniqueness as being divine or ensouled, it should hardly discount the need to examine how to adequately engage, enrich, and guide those learners toward their fullest potential. The potentials in holistic wisdom, drawn from a wider wealth of competencies, will prove essential in cultivating students' responses to dynamic and evolving global crises.

The Value of an Integral Education: A Mixed-Method Study with Alumni of the East-West Psychology Program at the California Institute of Integral Studies

Heidi Fraser Hageman[1]

Abstract: This sequential mixed methods study examined alumni's perceptions of an integral education in the East-West Psychology (EWP) program at the California Institute of Integral Studies (CIIS), and explored how they connected their unique, integral educational experience to personal and professional development. The findings revealed that their experience and understanding of integral education in EWP is mostly in alignment with the ideals of CIIS; namely, honoring multiple perspectives, the multidimensionality of being, and multiple ways of knowing were identified as key aspects of an integral education. The results of the study also point to the areas where the EWP program is doing well in terms of the education students expect and what they actually receive, and to the department's or Institute's learning edges. The most significant findings are the revelations of the need for: (a) more professional development, (b) more practical application opportunities, (c) more community/ mentor support for students' personal psycho-spiritual unfolding, and (d) more training regarding the language and expression needed to communicate the value of an integral education effectively with scholars/employers outside of CIIS.

Keywords: Graduate Education Evaluation, Integral Education, East-West Psychology, Personal Transformation, Nontraditional Curriculum, Spirituality in Higher Education.

Introduction

Almost five decades ago, in conjunction with shifts in collective consciousness like the counterculture and civil rights movements, a small graduate school in San Francisco was founded by Dr. Haridas Chaudhuri, a Bengali philosopher, and his wife Bina. California Institute of Asian Studies, today known as California Institute of Integral Studies (CIIS), was unique for the time, and still is to this day. There, an integral approach to education was implemented, a method of educating that (a) meets students where they are and honors each individual psycho-spiritual

---

[1] Heidi Fraser Hageman completed her Ph.D. in East-West Psychology (EWP) at the California Institute of Integral Studies (CIIS). Her doctoral research focused on exploring an integral education at CIIS through surveying and interviewing alumni from the EWP program about the personal and professional value of their non-traditional graduate degree. Currently, Heidi co-teaches the foundational Academic Writing Skills course at CIIS, as well as Research Colloquium and Qualitative Research in the EWP department, where she also resides as program manager. Passionate about lifelong learning, teaching that nurtures student development along multiple lines of intelligence simultaneously, research in higher education concerning student learning objectives and outcomes, and progressive models of educating, she aspires to assist students in understanding the value of their integral education and how to effectively communicate that to circles outside CIIS.

unfolding, (b) honors the multidimensionality of being and encourages simultaneous, balanced development of these aspects (e.g., physical, vital, emotional, intellectual, spiritual), (c) honors multiple ways of knowing (e.g., intuitive, cognitive, somatic), (d) honors multiple perspectives, even those contradictory to one's own, and (e) commits to social and environmental justice. Such a model is inspired by the creative and harmonious living developed and expanded upon by Chaudhuri, derived from principles of Integral Yoga articulated by Aurobindo Ghose and Mirra Alfassa, who were more commonly known as Sri Aurobindo and the Mother. The integral worldview and philosophical significance of these founding aspirations will not be the focus of this paper, but are written about by other integral educators (e.g., Chaudhuri, 1965, 1974, 1977; Ghose & Alfassa, 2006; Shirazi, 2005, 2011; Ryan, 2005; Subbionodo, 2011; Wexler, 2005, 2011; Fraser Hageman, 2015, etc.); though, they are worth noting here, as this ancestral lineage, along with its founding vision and principles, distinguishes CIIS from all other progressive/alternative models currently in practice in higher education in the United States.

One program in particular, one of the oldest programs at the Institute, East-West Psychology (EWP), sought to explore an integration of Eastern wisdom traditions and Western Psychology and what it would look like to bring these diverse worldviews into dialog with each other; it was a marriage of psychology and spirituality, as it were, when in the mainstream the two had been divorced. Today EWP has evolved from bridge to hub, a meeting place for seekers of truth from all walks of life from all over the world. What would the value of such a degree hold? The present study sought to understand this more deeply.

Description of the Study

This research explores the nature of an integral education, and its personal and professional value, from the vantage point of those who completed an advanced degree in the EWP program at CIIS. Specifically, a sequential mixed-method research design that utilized a mixed-data survey, as well as semi-structured, in-depth interviews, was implemented to gather EWP alumni perspectives on: (a) how alumni perceived the personal, interpersonal, and transpersonal domains of his or her experience while, and since, completing a master's or a doctorate, (b) the characteristics of an integral education, (c) the EWP degree experience and its connection to personal transformation and professional development. These alumni perspectives were collected with the aim of assessing (a) how EWP graduates understood the ideal nature of an integral education, (b) how well they felt the department offered that ideal or not, and if so, to what extent, (c) how alumni felt their graduate education experience in EWP contributed to their personal development, and (d) how alumni felt their experience in EWP contributed to their professional development up until now. The main goal of investigating EWP alumni perspectives on the value of their non-traditional graduate education was to reveal the benefits and pitfalls of such a non-traditional program, from the perspective of those who completed their degree.

Overview of the Research Design

In this sequential mixed-method design, multiple angles were examined concerning the personal and professional value of earning an M.A. or Ph.D. in EWP. In the first phase, a mixed-data survey was used to collect both quantitative and qualitative data concurrently. In the second phase, 10 participants from the first phase volunteered to participate in a qualitative interview, and were given the opportunity to evaluate their EWP experience in the context of their life before, during, and following the pursuit of a graduate education in EWP at CIIS. The Likert scale in Phase 1 was analyzed using *SurveyMonkey*, and content analysis was used to process both the responses to the open-ended questions in the first phase, as well as the interview transcripts from the second phase. Following the data analysis, participants who were involved with Phase 2 were given the chance to reflect on the findings, and to add or omit anything they deemed necessary, for validity purposes.

Description of Participants and Recruitment Procedures in Phase 1: Quantitative Phase

In the first phase of the research, a mixed-data survey, utilizing both a five-point Likert scale and three open-ended questions, was created using *SurveyMonkey* (See appendix A). Subsequently, a link to the survey, along with a recruitment letter, was distributed through the CIIS Alumni Association. Although the current sample does not reflect the entire EWP alum pool on record (N > 300), the Alumni Association had 161 email addresses for EWP alumni. From this sample of convenience, 47 participants completed the survey, yielding a return rate of 29%. The participant population varied in age, ranging from 25 to 74, with 81% being 35 to 64 years old (N = 38). 55% of the participants identified themselves as female (N = 26) and 40% as male (N = 19); two participants chose not to disclose that information. 51% of alumni (N = 24) surveyed completed their master's in EWP, while 47% earned a doctorate (N = 22); one person did not respond to this inquiry, but indicated the year they graduated from EWP. Forty percent of participants (N = 19) came to EWP with a psychology background, 19% studied in the traditional sciences (N = 9), and some had backgrounds in English literature (N = 3), and philosophy and religion (N = 6). Five participants (11%) in the first phase of the study were already CIIS alumni prior to becoming one of EWP as well. The range of participation was broad; the eldest EWP alumni who participated in the survey graduated in 1976, and the most recent in 2013.

Analysis and Interpretation

The first five questions on the scale were demographic in nature. Specifically, participants were asked: (a) whether they identified male or female, (b) their age range, (c) what their studies encompassed prior to commencing their course of study in EWP, (d) and the degree level completed in EWP, and (e) about the nature of their spiritual practice, however each chose to define that. The responses to these five questions were tallied, and the question concerning prior studies and spiritual practice were examined for threads of commonality. Figure 1 is a visual summary of the demographic data collected.

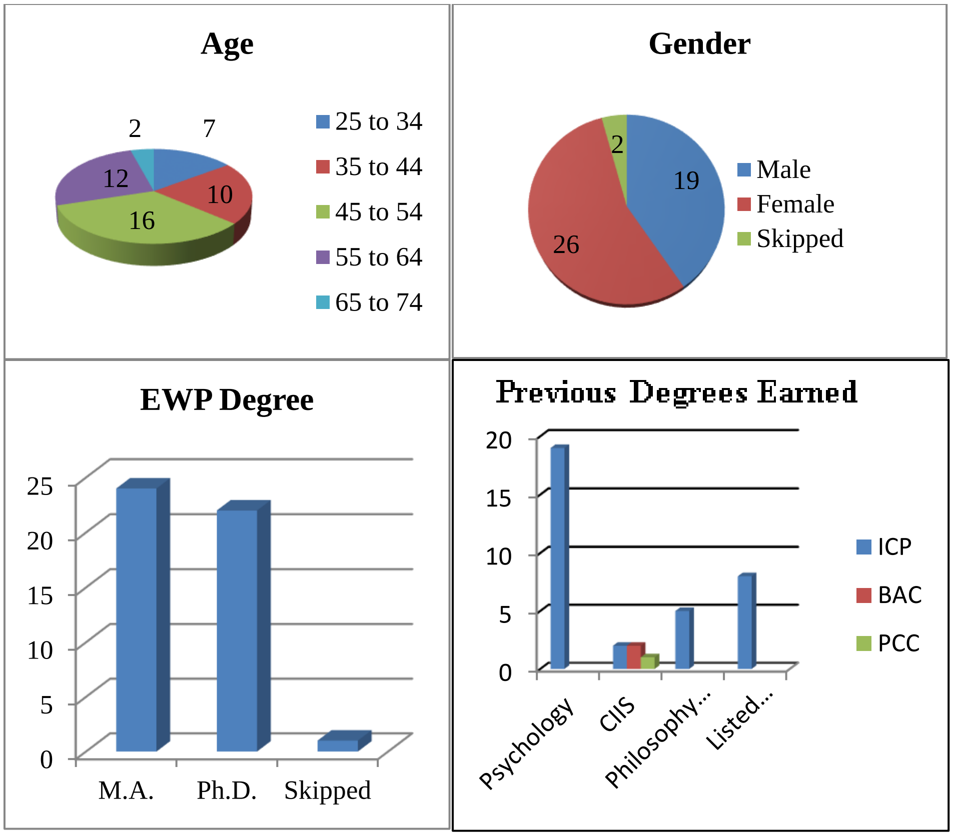

Figure 1: Summary of Demographics.

The Likert scale comprised the quantitative aspect of the first phase of this study. There were 40 statements organized into three categories: transpersonal, interpersonal, and personal. The categorization was used as a means to explore the participants' experiences in the context of the three dimensions of integral psychology as described by Shirazi (2005). The participants were asked to reflect on these statements as alumni, and as such, the time that had passed since they graduated varied among participants. The results of the data collected from the scale were organized into tables, which are reported below. Specifically, the responses were looked at in the order that they appeared in the scale, as separated by category, and by frequency. For example, the statements that respondents agreed with the most, and those that were agreed with the least, were highlighted.

The last three questions on the mixed-data survey were open-ended; this approach was used to give an opportunity for participants to express their experience in their own words. The responses to each of the last three questions were copied from each individual survey and pasted in a separate text document, one document for each question, so that every response to each of the open-ended questions would be all together in one place. Once the document was created with all the individual answers together, the responses were read through in their entirety and a summary of the open-ended responses was created as a way to explicate the threads of commonality that were revealed in participant’s open-ended responses. These threads manifested both as repeated words or phrases, and some unique responses were revealed as well. These responses were then organized into different categories (see Table 5 for a summary of the open-ended response results).

Description of Participants and Recruitment Procedures Phase 2: Qualitative Phase

In Phase 2 of the research, the 47 Phase 1 participants were invited to contact the researcher if there was a desire to dig more deeply into the inquiry underway, to schedule a semi-structured, in-depth, qualitative interview. Ten people responded to this call and reached out, willing to share their story. Subsequently, 10 interviews were conducted in-person or via Skype. The participants who availed themselves to the second phase of this project were both M.A. (N = 6), and Ph.D. (N = 4) alumni of the EWP program.

Like in the mixed-data survey, there was a range of alumni participation. The diversity of alumni who were interviewed was synchronistic; in other words, there was a meaningful coincidence concerning the qualitative sample. Although the sample was one of convenience, the pool somewhat reflected the varied and fluctuating focus of the department over the years since its inception. The earliest alumni interviewed graduated in 1986, and the most recent was in the graduating class of 2013. To maintain complete confidentiality and anonymity of participants, particulars will not be disclosed, however, there was an international roster of identities reflected in the pool of interview participants, with folks identifying as both male or female, and having Western or non-Western backgrounds.

Analysis and Interpretation

The semi-structured interviews were transcribed and the transcriptions of the interviews were content analyzed for themes. Both the content, such as what is said, and the form, such as plot structure of the story, were taken into consideration. The interview recordings were listened to multiple times to assure accuracy in the transcription, and then read and reread to see into the revelatory patterns. “Topics that stand out are usually characterized by their high frequency of appearance, proportional length, or vividness in the text” (Lieblich, Tuval-Mashiach, & Zilber, 1998, p. 73). Emergent themes concerning EWP alumni experiences were considered through this interpretive evaluation strategy suggested by Lieblich et al. (1998).

A thick-rich description was the aim in order to further address internal validity (Merriam, 1995). Every pause, um, laugh, and cry was documented. Boldface was used in the transcript to indicate words or phrases emphasized by the participant. Listening to the interview once through, before beginning the transcription process, gave the researcher a chance to reacquaint with the participant prior to the process of transcription. Once the interview had been transcribed, it was read four times. Time was also be taken away from the transcriptions before each subsequent reading, to give space for the development of further insight from the processes of gestation and indwelling, and what would potentially arise from the unconscious and dream states.

Each interview was looked at separately to first see what meaningful statements and phrases showed up for each of the 10 individual participants. "Qualitative coding, the process of defining what the data are all about" (Charmaz, 2006, p. 43) was used in the analysis portion of the second phase of this study. "Coding means naming segments of data with a label that simultaneously categorizes, summarizes, and accounts for each piece of data" (p. 43). After completing two of the four readings of each interview, the third and fourth readings were specifically geared towards organizing the participant's words into groups and articulating the codes for each group of data. The data was grouped by looking for similarities or threads in each individual participant's experiences, with consideration for frequency, length, and/or vividness, as previously suggested by Lieblich et al. (1998). The analysis of each participant’s interview transcription included a summary of their biographical information, as a way to offer the story of the person behind the data collected. For the sake of allowing interview participants to remain anonymous, these transcripts will not be included here. After each interview was looked at individually, the 10 transcripts were analyzed together, to determine overarching themes across interviews. (See Table 6 for a complete list of major and minor themes).

Phase 1: Quantitative Results Report

The Phase 1 results are comprised of two concurrent components: collection of demographic information and Likert scale, and open-ended questions.

The Quantitative Component of Phase 1: Likert Scale

The 47 participants who completed the survey were asked to rank the degree to which they agreed or disagreed with 40 statements concerning their EWP education. There was also the option for people to respond "Neither agree nor disagree." The following numerical values were used for calculation of each individual response:

Strongly Disagree	1
Disagree	2
Neither agree nor disagree	3
Agree	4
Strongly agree	5

The rating average for each response was calculated by dividing the total score for each question by the number of responses to that question. The average rating results and the median for each statement on the scale are summarized in Table 1. The list of statements in Table 1 begins at number six because prior to starting the scale, participants were asked to fill in some demographic information for example, age, gender, previous degrees earned, and whether they received an M.A. or Ph.D. in EWP. Also, participants were asked to briefly articulate the nature of their spiritual practice, orientation, and/or discipline, however they defined that. These first five pieces of the survey were optional.

Table 1: Overview of Transformation Evaluation Ranking Scale

Q#	*Rating Average*	*Median*	*Question Details*
Q06	3.30	3	EWP helped me develop a regular spiritual discipline.
Q07	4.11	3	Since completing my degree in EWP, I embrace an integral worldview.

Q08	4.06	3	The education I received from EWP helped me develop new levels of emotional maturity.
Q09	3.78	3	The education I received from EWP has helped me access my intuition.
Q10	4.22	3	My EWP education engaged the various aspects of my being.
Q11	4.13	3	Since completing my degree in EWP, my sense of self has expanded, allowing for more authentic spiritual expression.
Q12	4.09	3	My education in EWP taught me to support others in their psycho-spiritual transformation process.
Q13	4.02	3	EWP offered me an Integral Education.
Q14	3.81	3	My EWP education made it possible to relate to all beings more authentically.
Q15	3.59	3	Learning about psycho-spiritual disciplines inspired me to develop a personal, regular self-care practice.
Q17	3.62	3	As a result of my education, I actively seek opportunities to grow spiritually.
Q18	3.96	3	As a result of my EWP education, my ability for authentic self-expression improved.
Q19	3.79	3	I became more mindful as a result of my education in EWP.
Q20	4.11	3	My relationship with the sacred (however you define that) deepened throughout the program.
Q21	3.83	3	My education in EWP has inspired me to experience life as an ever-unfolding evolution of consciousness.
Q22	3.41	2	As a result of my education in EWP, I am more mindful of my impact on the environment.
Q23	4.17	3	As a result of my education in EWP, I was taught to honor multiple ways of knowing.
Q24	4.09	3	In my experience, EWP fostered my psycho-spiritual transformation.
Q25	3.62	3	Being emotionally supported while completing my degree contributed to my spiritual/transpersonal development.
Q26	3.55	3	I learned how to experience embodied knowing as a result of my education in EWP.
Q27	3.43	3	My education in the EWP program increased my capacity for genuine intimacy.
Q28	3.60	3	While in the program, I felt part of a spiritual community.
Q29	3.94	3	My education in EWP has helped me actualize my highest potentials.

Q30	4.17	3	The people I met during the program were instrumental to my growth.
Q31	3.70	3	Throughout the program, in general, I felt emotionally supported during class time.
Q32	3.48	3	What I learned in the EWP program catalyzed a significant change in my lifestyle.
Q34	3.77	3	The EWP program catalyzed a significant change in the way I relate to the world.
Q35	3.63	3	My EWP education has been indispensable to my professional development.
Q36	4.02	3	Being a part of EWP, I became part of a community which honors multiple worldviews.
Q37	3.66	3	My EWP experience catalyzed a significant change in the way I relate to others.
Q38	3.96	3	My education in EWP helped me to develop an expanded sense of self.
Q39	3.70	3	My education in EWP fostered the development of interpersonal communication skills.
Q40	3.81	3	I was challenged to become aware of and reassess my worldview assumptions through my EWP education.
Q41	3.72	3	My education in EWP helped me become more aware of the underdeveloped aspects of my personality.
Q42	3.68	2	Through my education in EWP I learned to respect worldviews contradictory to my own.
Q43	3.38	3	My education in EWP awakened in me a sense of global citizenship and responsibility.
Q44	3.91	3	My education in EWP taught me to honor the multidimensionality of existence.
Q45	4.23	3	In retrospect, I had a positive experience of EWP overall.

Of the 40 statements participants were asked to rank, there were 13 designated to address each of the three dimensions of life experience in integral psychology: the personal, interpersonal, and transpersonal (Shirazi, 2005). The final statement on the scale, "In retrospect, I had a positive experience of EWP overall" was categorized as "other," since it is a broad, overarching statement regarding the program itself rather than an inquiry into a specific aforementioned aspect of being.

In Table 2, the questions have been categorized, and presented in the order of average rating from high to low, and the main point of each statement is listed.

Table 2: Categorization of Likert Scale Statements: Personal (P), Interpersonal (I), and Transpersonal (T)

Q#	*Rating Average*	*Category*	*Summary of key points in the question*
Q10	4.22	P	engaged various aspects of being
Q23	4.17	P	taught to honor multiple ways of knowing
Q08	4.06	P	helped develop new levels of emotional maturity
Q38	3.96	P	helped develop an expanded sense of self
Q29	3.94	P	helped actualize my higher potentials
Q40	3.81	P	challenged to become aware of and reassess my worldview assumptions
Q19	3.79	P	developed mindfulness
Q41	3.72	P	increased awareness of underdeveloped aspects of myself
Q42	3.68	P	learned to respect worldviews contradictory to my own
Q35	3.63	P	indispensible to my professional development
Q26	3.55	P	learned to experience embodied knowing
Q32	3.48	P	learning catalyzed a significant change in my lifestyle
Q30	4.17	I	people I met were instrumental to growth
Q12	4.09	I	learned how to support others psycho-spiritual process
Q36	4.02	I	part of a community that honors multiple worldviews
Q14	3.81	I	authentic relating, support of others psycho-spiritual growth process
Q34	3.77	I	change in relating to the world
Q31	3.70	I	felt emotionally supported in class
Q39	3.70	I	developed communication skills
Q37	3.66	I	catalyzed change in relating to others
Q28	3.60	I	felt part of a spiritual community
Q27	3.43	I	increased capacity for intimacy
Q43	3.38	I	awakened sense of global citizenship
Q16	3.23	I	as an alum, still feels part of community
Q11	4.13	T	sense of self expanded, allowing for more authentic spiritual expression
Q07	4.11	T	now embrace an integral worldview
Q20	4.11	T	deepened relationship with the sacred
Q24	4.09	T	fostered my psycho-spiritual transformation
Q13	4.02	T	offered me an integral education

Q18	3.96	T	ability for authentic self-expression increased
Q44	3.91	T	taught to honor the multidimensionality of existence
Q21	3.83	T	inspired me to experience life as an ever-unfolding evolution of consciousness
Q09	3.78	T	helped access intuition
Q25	3.62	T	emotional support contributed to spiritual development
Q22	3.41	T	more mindful of impact on the environment
Q06	3.30	T	developed a regular spiritual practice
Q45	4.23	OTHER	overall, I had a positive experience

Table 3 shows the 15 statements, out of 40, in which respondents either agreed or strongly agreed with least frequency, while Table 4 reflects the 15 statements that respondents agreed or strongly agreed with the most frequency. These two tables are organized from high to low; in other words, for example, in Table 3, the statement that people agreed with the least was number 22, "as a result of my education in EWP, I am more aware of my impact on the environment." Categorically speaking, participants were least likely to agree or strongly agree with certain statements from each category: Transpersonal (N = 4) Interpersonal (N = 6), Personal (N = 5). Interestingly, all three dimensions were rated somewhat similarly, which indicates that one was not privileged over the other.

Table 3: Statements with the Lowest Agree/Strongly Agree Response Rate

Q#	***Category***	***Respondents who Agreed or Strongly Agreed***	***Total Respondents***	***Percentage of Agreement***	***Question Details***
Q28	I	30	47	64%	While in the program I felt part of a spiritual community.
Q25	T	30	47	64%	Being emotionally supported while completing my degree contributed to my spiritual/transpersonal development.
Q42	P	29	47	61%	Through my education in EWP I learned to respect worldviews contradictory to my own.
Q39	I	28	47	60%	My education in EWP fostered the development of interpersonal communication skills.
Q17	T	28	47	60%	As a result of my education, I actively seek opportunities to grow spiritually.

Q15	P	27	46	59%	Learning about psych-spiritual disciplines inspired me to develop a personal, regular self-care practice.
Q26	P	26	47	55%	I learned how to experience embodied knowing as a result of my education in EWP.
Q27	I	25	47	53%	My education in the EWP program increased my capacity for genuine intimacy.
Q35	P	25	46	53%	My EWP education has been indispensible to my professional development.
Q6	T	24	47	51%	EWP helped me develop a regular spiritual discipline.
Q32	P	24	46	52%	What I learned in the EWP program catalyzed a significant change in my lifestyle.
Q16	I	22	47	47%	As an alum, I still feel part of the EWP community.
Q43	I	22	47	47%	My education in EWP awakened in me a sense of global citizenship and responsibility.
Q33	I	21	47	45%	My education had a noticeable positive effect on the quality of my relationships.
Q22	T	20	46	43%	As a result of my education in EWP, I am more mindful of my impact on the environment.

Table 4 shows which of the statements out of 40 participants agreed or strongly agreed with most frequently; the table is in order from high to low. It is interesting to note which categories the statements that were most agreed or strongly agreed with fell into: Transpersonal (N = 6), Personal (N = 5), and Interpersonal (N = 3); here it seems that agreement is more prevalent in both the transpersonal and personal domains. Eighty-nine percent of the participants either agreed or strongly agreed with the final statement on the scale, "in retrospect, I had a positive experience of EWP overall," which is categorized as "other" because it was included in the scale to serve as a reflection on the overall experience of the education in EWP. Although this is significant, a "positive experience" does not take into account the three different categories, personal, interpersonal, and transpersonal.

Table 4: Statements with the Highest Agree/Strongly Agree Response Rate

Q#	*Category*	*Respondents who Agreed or Strongly Agreed*	*Total Respondents*	*Percentage of Agreement*	*Question Details*
Q36	I	42	47	89%	Being a part of EWP, I became part of a community which honors multiple worldviews.
Q45	Other	42	47	89%	In retrospect, I had a positive experience of EWP overall.
Q23	P	41	47	87%	As a result of my education in EWP I was taught to honor multiple ways of knowing.
Q38	P	37	47	79%	My education in EWP helped me develop an expanded sense of self.
Q7	T	36	47	77%	Since completing my degree in EWP, I embrace an integral worldview.
Q19	P	35	47	74%	I became more mindful as a result of my education in EWP.
Q18	T	35	47	74%	As a result of my EWP education, my ability for authentic self-expression improved.

The Qualitative Component of Phase 1: Open-Ended Questions

The participants who completed the Likert scale were also invited to reflect on their EWP learning experience in their own words. At the conclusion of the ranking scale participants were asked to articulate their thoughts concerning the characteristics of an integral education, as well as how their graduate education in East-West Psychology contributed both to personal and professional development, if this was applicable. Forty-six of the 47 participants who completed the scale opted to answer the open-ended questions— one simply said "pass" on all three— and although some themes were revealed, the answers to these questions also reflect a diversity of expressions. A summary of the major themes from the open-ended responses can be found in Table 5, as well as the number of times each occurred (in parentheses).

Table 5: Summary of Open-ended Results

Question Details	**Themes**
In your view, what characterizes an Integral education?	Theme 1: Honors Multiple Worldviews (13) Theme 2: Honors the Multidimensionality of Being (11) Theme 3: Honors Multiple Ways of Knowing (10) Theme 4: Psycho-spiritual Unfolding (8) Theme 5: Integration (5)

Please describe how your EWP learning experience and degree completion contributed to your personal development (If not applicable simply state that).	Theme 1: Expanded sense of self/Deepened Self-Understanding (23) Theme 2: Transformation/Development already in progress (7) Theme 3: Encouraged Exploration of Multiple Ways of gaining valid knowledge (7) Theme 4: Growth/Maturation (6) Theme 5: Not Applicable (5) Theme 6: Ph.D. process (4)
Please describe how your EWP learning experience and degree completion contributed to your professional development (If not applicable simply state that).	Theme 1: Not Applicable (14) Theme 2: Academic/Scholarly (9) Theme 3: Indirect Effect (6) Theme 4: Deepened Current Work (5) Theme 5: One Step on the Path (4)

Phase 2: Qualitative Results Report

Ten people agreed to go a little deeper into this inquiry into earning a graduate degree in EWP at CIIS and semi-structured interviews, in-person and via Skype, were conducted. Through the interviews, the aim was to have participants tell their EWP story; specifically, the curiosity that drove this work was the exploration of who these EWP alumni were before, during, and after their experience of earning a graduate degree in the program. In addition to this grand-tour question, there were 10 questions prepared to guide participants through this inquiry as well. In the spirit of EWP, all interviewed participants were invited to sit in mindful silence for a few minutes prior to the start of the interview with the researcher, as a way to encourage thoughtful and intentional presence during the interview itself. A summary of individual interview themes follows.

Summary of Interview Themes

There were certain themes that came up in multiple interviews and these are expressed in Table 6. The overarching themes are organized from high to low, with the number of occurrences noted in the table referring to how many times each individual interview theme showed up during the entire qualitative phase of the research. In other words, for example, seeker/self-directed learner was an individual interview theme that was apparent in each participant's transcript, so Table 7 indicates that particular individual theme to have appeared 10 times during the second phase of the project. The themes are categorized as major or minor, depending on how many instances that particular theme arose.

Table 6: Overarching major and minor themes from all interviews

Major themes	Theme 1. Seeker/Self-directed Learner (10) Theme 2. Positive Aspects of EWP (7) Theme 3. Takeaways (7) Theme 4. Synchronistic Unfolding (6) Theme 5. Spiritual Emergence/Emergency (4) Theme 6. Critiques (4)
Minor themes	Theme 1. Integral Worldview Foundation (3) Theme 2. What EWP Lacked (2)

	Theme 3. No Bridge (2) Theme 4. Shadow Side of Spirituality (2) Theme 5. Double Life (2)

Seeker/self-directed learner. A person who displayed a strong will to learn through an ongoing seeking to satisfy a passionate curiosity to know thyself was considered in light of the first major theme, seeker/self-directed learner. This theme also is considered as a characteristic of one's lifestyle, a characteristic that became apparent in all 10 participants' stories when asked about their life before their EWP graduate education experience. For example, all 10 interview participants spoke to the time prior to EWP and CIIS in a particular way. As each described life before EWP, the tendency to have a thirst for self-knowledge became evident, and a thread of commonality concerning previous studies and interests was present: all could be related to the intentional search for psycho-spiritual growth. Jean worked full time, yet on her own, she was taking various classes from all kinds of traditions from the Enneagram to grief work, to mythology. Susan was a nun who was deep into self-study through spiritual practice; she noted exploring many different wisdom traditions simultaneously, and while completing her master's in counseling psychology, she was reading humanistic and transpersonal psychology on her own. Charles said that his home country held education in high regard, and these times of learning were significant and meaningful to him; for example, many a night in college he would stay up until the wee hours and talk with his friends about their aspirations and what social justice projects they sought to implement. Ariel reported a spontaneous spiritual awakening and how she was very broken down by it; however, she also noted that it was "not in a bad way, just you know what happens when you start seeking" (Ariel's Transcript, p. 1). At the undergraduate level, Duncan declared two majors, in sociology and philosophy, and he was deeply embedded in the local music scene while he pursued his traditional studies. He also noted reading one or two books a week once he discovered Fields Bookstore, a shop in San Francisco that specializes in esoteric and spiritual wisdom traditions. Grace went to a non-traditional high school, in order to interweave her academic work with her love of theatre. Psychology and spirituality have long been interests of Lily, and she was studying Jung and Wilber on her own, a pursuit that actually led her to find CIIS. Phoenix had a regular *Vipassana* practice for nearly a decade, worked with plant teachers, as well as studied in the PCC department at CIIS for his master's. Holden traveled extensively in Asia and Europe, a venture that began when he was 29 and "feeling antsy" (Holden's transcript, p. 2). Theodore reports being a seeker all his life, and that seeking transformation is part of his recovery; "it is vitally necessary in order to actually escape from your addiction" (Theodore's transcript, p. 1). This tendency to search for opportunities to gain self-knowledge and experience psycho-spiritual growth is also apparent in each of the participant's decisions to embark on the journey and complete the course to earning a graduate degree in EWP.

Positive aspects of EWP. The positive aspects of earning a degree in EWP refers to the highlights and how people described what they valued most about their experience while in the program. Grace, for example, found it valuable that her teachers engaged with her, and she felt fully supported in following whatever she was passionate about. She also loved the flexibility to take courses in other departments, and felt that the program truly honored each student's individuality. Lily echoed Grace's feeling of being supported, and Theodore too, was just thrilled to find a beloved community, a flock of birds of his own feather, one in an "accepting, nurturing, familial kind of environment" (Theodore's transcript, p. 12). Ariel appreciated the "gentleness and receptivity…[and the] soft welcoming and reassuring" atmosphere of the department that she discovered upon her arrival, and it is this initial vibe of the program that even allowed her to even begin her graduate education in the first place (Ariel's transcript, p. 6). Like Grace, Ariel also appreciated the flexibility to take courses from across departments within the Institute while working towards her degree in EWP. Jean and Holden spoke highly of certain courses; specifically, Jean mentioned Spiritual Counseling Skills, and Holden noted Integral Approaches to Dreams, Comparative Mysticism, and Eastern Theories of Self, Mind, and Nature as highly influential. Phoenix and Grace expressed gratitude for the foundational grounding gained in the Eastern theories course as well.

Takeaways. The takeaways are participants' reports of what they feel they received from earning a degree in EWP. There were seven participants who reflected on the takeaways. Holden felt that he broadened and deepened his understanding of the history of Eastern religions and how they connect with the nascent field of transpersonalism, and "things that used to be sort of loose and floating out there, now…a much stronger foundation from a theoretical and religious standpoint" (Holden's transcript, p. 12). He also spoke of an expanded awareness of the distinctness and inseparable inner and outer realms of experience, and was able to use the knowledge he gained in the course Cosmos and Psyche to critically reflect on non-dual experiences that he had prior to studying in EWP. Also, Duncan reported that he was able to take away a more logical and analytical approach to studying traditions that are often dubbed "just new age" (Duncan's transcript, p. 5), and are at risk of nebulousness. Theodore asserts that completing the program allowed for a deepened self-maturation. Grace said that since completing a degree in EWP she now has the ability to hold perspectives that may be new or contrary to her own, as well as an increased engagement with and integration of her wounds and the shadow aspects of her personality. Lily had the realization of being out of touch with her body, and after coming to CIIS and enrolling in EWP she began to actively come into contact with this disconnection, as well as other blind spots that she had. Besides increased somatic and emotional awareness, Lily also felt that her EWP experience helped her to connect with and better articulate one of her biggest passions: human development. Further, she deepened her understanding of what she envisions as her livelihood. She also reported a greater understanding of her intuition. Phoenix too emphasized that one of the gifts EWP gave him was a greater somatic awareness, which helped him to recognize that his mind tends to dominate his experience. He began to really value the body and its wisdom after the embodied spiritual work he completed while earning a Ph.D. in EWP. These are some of the examples of how people described what they received from the educational experience of earning a degree in EWP, which is distinct from the positive aspects of EWP because of its deeper specificity.

Synchronistic unfolding. Synchronistic unfolding refers to the particular way in which some participants described meaningful coincidences that occurred in and throughout their lives, as well as the capacity to see an interconnection and a larger picture through making meaning of these events. Some participants even used the term synchronicity when talking about certain moments in their life. For example, Lily recalled a time when she signed up for a class, and right at the last minute she could not attend; she ended up taking another class, the only class left, and she mentioned that "there was something bigger" at work orchestrating that shift in coursework during her final semester in the EWP master's. Ariel said that she was brought to CIIS "synchronistically" (Ariel's transcript, p. 1). Additionally, it was through her work at the café that she just happened to hear about another job opening of interest from a friend who was leaving his position, and she soon after gained employment on a farm, which aligned with her passion to promote awareness of non-GMO and pro-organic movement. Jean told a story about how just after she had begun taking classes focused on personal development in her hopeful home country she returned to the place of her birth to work on getting her visa. While she was visiting, there happened to be a high school reunion. This was very odd; she said "we never ever meet up again…we don't care, you just leave school" (Jean's transcript, pp. 6-7). She felt that is was extremely ironic that her favorite teacher from high school, "the first person who actually saw me as a human being," mentioned her current teacher's name and was well acquainted with them. Additionally, she described that upon returning home from the school reunion, she enrolled in and was accepted into a course that usually has a 6-month waiting period, and instead she was able to attend the following weekend, since there was one space that mysteriously opened up, and her grandmother had just given her a birthday gift for the exact amount of the course. Susan also described certain stories of her life in a particular way, in a way that she described as unfolding meaningfully. She was admitted into the EWP program in less than a week's time; she also asserted that she had no idea where she would complete her internship hours and somehow received the grace of being awarded a teacher's assistant position, which then led to a co-teaching/adjunct faculty role in the subsequent semester, and in turn paved the way to her teaching her own courses at that school, eventually leading to her becoming a program chair and creating her own integral degree program. Phoenix said that when he was in Asia, he ran into some CIIS professors who let him know about certain mentorship opportunities, which then led him to study in EWP with his eventual dissertation chair. He also said that he "happened to move close to one of the best massage schools in the country after graduation" and that his fruitless pursuit of a job in academia was a blessing because it showed him what his calling really was (Phoenix's transcript, pp. 9-10). Duncan's responses also reflected a synchronistic unfolding; for example, he moved to California to pursue music, but discovered CIIS while he was living in San Francisco, and decided to go back to school there. Additionally, he had been reading Stan Grof on his own time, and found out that he happened to be teaching two blocks from where he worked. The instances noted here may seem insignificant to some, but it is the way in which the participants made meaning of them as they told their stories is what makes them stand out in this research as the theme synchronistic unfolding.

Spiritual emergence/emergency. Spiritual emergence/emergency denotes non-ordinary states that participants reported experiencing, states that were spontaneous and not substance-induced. Holden recalls a time that he was hiking in the Himalayas and he felt a sense of oneness with the land and all that surrounded him; he said he felt "permeable as though I was connected to the animals, the mountains everything, it was just this wonderful sense of interconnectedness" (Holden's transcript, p. 3). He reported a similar experience in Scotland when encountering huge monoliths at the Ring of Brodgar; it was like "a psychic merging with one of the stones" (p. 4). Lily mentioned two instances where she was having a "peak experience," although she said one was "extremely ungrounded…I didn't really sleep or eat properly…it got really scary, like everything was so on all the time. I couldn't leave my house…stand bright colors or strong smells" (Lily's transcript, p. 5). Ariel experienced a similar intensity in her experience of emergence; she said she "had a big…spontaneous spiritual awakening *kundalini* episode" that left her "broken down" (Ariel's transcript, p. 1). Phoenix's spiritual emergence experiences were more subtle; he said "I started having these spiritual experiences…basically massive encounters in the dream state, and some synchronicities with entities that I would later define as my guides" (Phoenix's transcript,

p. 1). Although the quality of participants' spiritual emergence varied from positive to challenging, all these reports indicate encounters with a domain that is beyond ego understanding.

Critiques. Another overarching theme in the qualitative interview phase was critiques of EWP, and these often came with a disappointed or dissatisfied undertone. Duncan cited his surprise with the student body, stating that it "was kind of confusing and shocking…it was a lot more kind of Northern-Californian well-to-do…middle-aged people" and furthermore "the student body was very mixed…in the sense that there was a wide range of rigor" (Duncan's transcript, p. 3). The hefty student loans were also mentioned as a downside, although that has more to do with the Institute than the department. Jean felt that the master's was "an unfinished product" and "it wasn’t an academic experience" but a "concentrated form of inner work" (Jean's transcript, pp. 16-17). She also said that it did not provide her anything for a "professional basis" (p. 17), and she was troubled by the inappropriateness on the part of some of the faculty members in relation to students. Charles had much to say about EWP in terms of critique. He found "the climate anti-intellectual and…it did not address spirituality in [a] very systematic and detailed manner" (Charles' transcript, p. 3). Additionally, he felt that some of the professors "have taken a slice of their study and made it the end all be all… [and he] personally feels that they have basically killed the dream of Dr. Chaudhuri" (p. 3). Charles was also discouraged that the school openly advertises allegiance to the integral educational vision of Sri Aurobindo and The Mother, yet he came here is did not find that allegiance present, and he noted this "lurking as a huge shadow of CIIS" (p. 5).

In contrast to other participants who noted the EWP community in a positive light, Ariel felt this is where the department could further develop, stating outright "EWP was not very good at community” (Ariel's transcript, p. 3). Additionally, she noted “there were a few people with whom I entered [that] transferred out of EWP because of issues about: what am I going to do with this?" (p. 3). Here, there is a hint pointing toward the uncertainty of what comes next professionally after earning a degree in EWP. She also said "I don’t feel that EWP at the time was really teaching to race or gender or class awareness or social justice issues on a kind of practical…pedal to the medal kind of way" (p. 3). The aforementioned critiques theme concludes the summary of the major themes from the qualitative interview phase and a review of the minor themes from Phase 2 follows. These themes were categorized as minor because the number of times they manifested in participants' interviews was three or less (see Table 6 for complete list).

Integral worldview foundation. Three participants displayed characteristics that show an integral worldview foundation in their life; in other words, there are particular ways in which the three following participants show up in the world that can be linked to having adopted an integral worldview as their ontology and epistemology. Susan was very much influenced integral theory; not only by the work of Sri Aurobindo and The Mother, but Ken Wilber as well. Above all, how she communicates with herself, and her active seeking to know her calling, is very much aligned with the way integral yoga honors the unique unfolding of each individual soul. She spoke about how she sought self-knowledge in this way: "I just sat in meditation, and I said my sacred intention for this life is to be a vehicle for spirit" (Susan's transcript, p. 7). She also asserted that "integral is probably the most profound teaching that I got at CIIS, and integral within an evolutionary movement" and she went on to further elaborate, saying "so everything I've done in my life, both personally and professionally since then, has had an integral, evolutionary, unfolding foundation, perspective, emphasis…it’s the container through which I seem to experience and feel everything…and everything I teach" (p. 7). Charles also depicts a lifestyle and teaching philosophy aligned with the integral vision of Sri Aurobindo and The Mother specifically. He said " I am very respectful to all spiritual teachers…across traditions…the way I see [it] is that they [have] access to a particular truth and that truth is important because it came from their own experience of pursuing the divine" (Charles' transcript, p. 6). The integral worldview foundation also showed up in his description of his approach to teaching students: "it is like truly honoring their inner constitution and giving them what would really benefit them…which will actually…help them walk a path which is in accordance with the seekings of their inner being" (p. 9). Duncan also mentioned that his work in EWP affected everything he does in life, which includes teaching and mentoring, as well as engagement within his music community. For example, although he is deeply involved with his music nowadays, he recently wrote a book about music production. Interestingly, he included a philosophical and historical context for the reader, and connected the emergence of electronic music to what certain musicians were reading at the time, which included the works Sri Aurobindo, and D.T. Suzuki.

What EWP lacked. What EWP lacked was named a distinct theme from critiques because two participants specifically pointed to what was missing from their gradate experience in EWP rather than speaking indirectly about what they did not like, or what the program could do better, as with those classified as critiques of EWP. For example, Susan felt that the social dimension was underrepresented in the program; in other words, there was a lack of connection between the work being done at CIIS and how it could connect or be implemented in the world at large to address social issues. She mentioned that "they really didn't do much with the social, but it was sort of implied that…as we went up the ladder of integration, it would go towards social issues eventually [but] it didn't integrate it as much as I would want" (Susan's transcript, p. 7). Also, Lily noted that there was a lack of professional and practical skill development during the time she completed a master's degree in EWP. She would have benefitted from learning about "marketing and business tools" because "just because you have a passion and you think you're aligning with the universe's purpose for yourself doesn't mean shits going to happen" (Lily's transcript, p. 9). Moreover she said "the gap I was sensing in EWP was that we're not sensing that development needs to be within your space wherever you are" and she cites the example of attempting to teach students about nonduality when they do not even know what it is like to be in their body; "it's a huge huge very dangerous spiritual bypass" (p. 6). Two other participants cited that EWP lacked a bridge from graduate school back to the mainstream, work-a-day world, however this warrants distinction as its own theme because of the intriguing specificity.

No bridge. A bridge may also be something that EWP lacked, but this theme was distinguished because of how two participants specifically spoke of their experience of trying to become gainfully employed upon graduating with a Ph.D. in EWP in a specific way wherein they both describe no clear cut path from graduate school to working professional. Both Holden and Phoenix also mentioned the difficult transition from their EWP graduation to the mainstream workforce. Specifically, Holden said that although his degree is "reputable," it has not been "very applicable in a mainstream sense" (p. 1) as of yet. He describes his job search since graduation in this way: "if you're spending your time chasing things, like a job in transpersonal psychology… [you're] susceptible to pent up frustration which inhibits the flow of the passion and inspiration" (p. 13). Similarly, Phoenix noted of his EWP experience that "there was something of it being like a womb-like container…and I feel there has been sort of a shock of coming out of there…coming out of

EWP there was not a bridge to the world" (Phoenix's transcript, p. 8). Additionally, he said "the nature of the work that we do in EWP is, it is very unlikely that you're going to have somebody knocking on your door saying whatever it is you do, I heard you're good, here's 60 dollars, just do your EWP thing for an hour" (p. 9). It is apparent here that not only does Phoenix feel there is a lack of a bridge, but, he is even unsure of how to describe what he can offer to the world after completing a degree in EWP.

Shadow of spirituality in higher education. Another minor theme could also be a subtheme of the overarching critiques theme that emerged concerning EWP; two participants specifically pointed to the shadow side of spirituality in higher education when they expressed certain aspects of their experience of the program. Holden said, "sometimes the ideals that are espoused at CIIS, the images people try to portray just don't match up…I think that's the shadow of CIIS. I think that people tend to forget their basic humanity sometimes in the process of espousing basic humanity" (Holden's transcript, p. 7). He noted several instances with different professors to support this point. Additionally, he said "when you go to a place like CIIS there are such high ideals and such high hopes and I think that [for] a lot of people it also brings out weird shit…I think there is a lot of unresolved angst at our school" (p. 11); he also mentions the pettiness and self-promoting nature of some faculty members, which is contradictory to spiritual and integral values of the Institute. Lily also noted a shadow side of spirituality in higher education. As previously mentioned, she talked about the danger of spiritual bypass, which could occur if you try to teach people about nonduality when they first have not even been able to experience their body first. She also said "when you don't deal with trauma through grounding, it is easy to go off into a bliss state and ignore your body" (Lily's transcript, p. 5), and she felt that this was not made explicit during her time in the program.

Double life. There were two participants who alluded to a disconnection between their career or work, and their pursuit of self-knowledge and personal growth through exploring psychological and spiritual traditions, a disconnection between their passion and how they made a living. Thus double life was used to describe this phenomenon articulated in their stories. Jean was deeply embedded in the world of finance; this route was very practical for her and she was making a great living. Yet she longed to study "other ways of seeing the world" (Jean's transcript, p. 5) and she did this often on her own time, reading and taking workshops on a wide variety of topics "from death and dying to grief counseling to healthy relationships to Reiki, anything alternative" (p. 6). Grace too spoke about a split between what she loved to do and how she made money. From a young age she reports "I've always had a double life" (Grace's transcript, p. 4) because as a theatre kid, she would go to school by day and "crew shows" (p. 4) by night. This way of being in the world continued when she was acting post-Julliard; she "had to work 9-5 to pay for acting," (p. 4) and most recently, all the while she worked on her degree in EWP she worked as a web consultant from home.

Results Summary and Discussion

The first phase of the present work gave a glimpse into the diverse perspectives of alumni who completed a degree in East-West Psychology in regard to the nature of their experience in the program on multiple levels (i.e., personal, interpersonal, and transpersonal); self-reports regarding the understanding of "integral education," as well as to what degree did the M.A. or Ph.D. in EWP contribute to personal and professional development were also collected. The demographic information gathered reflected a wide array of identities and the ranking scale revealed that participants for the most part agreed with the statements on the scale. The open-ended questions complemented the ranking scale data, since participants were invited to speak to aspects of the scale in their own words.

The second phase of the project enriched the first. The semi-structured, in-depth interviews allowed 10 participants the space to more deeply articulate the value of their degree in EWP, and explore who they were before, during, and after their degree completion. Of the 10 interviews, there were 23 individual interview themes that became apparent, and 11 overarching: six major and five minor themes. In a latter section, some of the major themes identified, the positive aspects of EWP, takeaways, and critiques of EWP, are further categorized, since individual participant responses varied concerning these three themes.

Quantitative Phase: Likert Scale

In the first phase, there were two data collection strategies used simultaneously. Initially, participants were asked to offer some demographic information, and complete a ranking scale, which included 40 statements. Each of the 40 statements on the scale following the demographic information was categorized as personal, interpersonal, or transpersonal; this was purposeful. The categories were used as a way to gauge alumni experiences concerning multiple dimensions of their experience in the context of their graduate education in the EWP program.

As evidenced in the results of the scale, EWP alumni were largely in agreement with all of the statements and an overwhelming 89% (N = 42) of participants agreed or strongly agreed that overall they had a positive experience in EWP. For example, even statement 22, "my education in EWP taught me how to support others in their psycho-spiritual transformation process," which had the lowest agree/strongly agree response rate of all the statements on the scale, still yielded a 44% (N = 20) agreement response rate, and this low agreement response rate was not highly disagreed with. However, 46% of participants (N = 21) neither agreed nor disagreed with the statement "as a result of my education in EWP, I am more mindful of my impact on the environment." This begs the question of clarity regarding the phrasing of the statement itself in regard to the exploration of the outcomes of earning a graduate degree in EWP, since more responses indicated participants were neither in agreement or disagreement, than disagreement or strong disagreement. There were however, a few statements that revealed some disagreement worth noting. Table 7 shows the percentage of neutral response rates and the disagree/strongly disagree response rates alongside the percentage of agreement rates for the 15 statements that participants agreed with least. Statements for which the disagree or strongly disagree responses exceeded the neutral response will be discussed in detail.

Table 7: Categorized Statements with the Lowest Agree/Strongly Agree Response Rate Alongside the Corresponding Neutral Response Rate Percentage and Disagree/Strongly Disagree Percentage

Q#	*Cate-gory*	*A/ SA RR*	*DA/SDA RR*	*Neutral RR*	*Total # of Responses*	*% A/SA Responses*	*% of Neutral Response*	*% of D/SDA Response*
Q28	I	30	9	8	47	64%	17%	19%
Q25	T	30	7	10	47	64%	21%	15%
Q42	P	29	3	15	47	62%	32%	6%
Q39	I	28	2	17	47	60%	36%	4%
Q17	T	28	5	14	47	60%	30%	10%
Q15	P	27	7	12	46	59%	26%	15%
Q26	P	26	8	13	47	55%	28%	17%
Q27	I	25	6	16	47	53%	34%	13%
Q35	P	25	8	13	46	54%	28%	18%
Q6	T	24	12	11	47	51%	23%	26%
Q32	P	24	6	16	46	52%	35%	13%
Q16	I	22	14	11	47	47%	23%	30%
Q43	I	22	6	19	47	47%	40%	13%
Q33	I	21	3	23	47	45%	49%	6%
Q22	T	20	5	21	46	44%	46%	10%

There were three statements participants disagreed or strongly disagreed with that are worth noting here, since the percentage of participant disagreement exceeded the neutral response rate. Statement 16, "As an alum, I still feel part of the EWP community," was the statement participants disagreed or strongly disagreed with the most: 30% of participants reported they did not feel part of the community as alumni (N = 14), when 47% agreed or strongly agree that they did. Although CIIS has an active alumni association, and EWP itself has bi-annual gatherings for all in the community, past and present, as evidenced in the response results of this statement on the scale, some people do not feel part of the community once they graduate.

Statement 6, "EWP helped me to develop a regular spiritual discipline," was another statement of interest, since it yielded a disagree/strongly disagree response rate of 26% (N = 12). Again, it would interest me to speak with these participants further; did they already have a spiritual practice developed prior to commencing their studies in EWP, or has EWP failed to support the development of a spiritual practice? In future studies, a clearer expression of what was initially attempted here may come in the form of two distinct questions, one inquiring into participants experience of the spiritually based, community-oriented nature of the program, and the other asking participants more directly about the connection between studying in EWP and its connection to each individual's spiritual practice.

Additionally, when asked statement 27, "while in the program, I felt part of a spiritual community," 19% (N = 9) of participants disagreed or strongly disagreed, more than those who were neutral, or in agreement. This is interesting to note since the two statements just mentioned both inquired into a similar area of exploration: to what degree the course of study EWP impacted the development of a spiritual discipline, and to what degree did participants feel they were learning within a spiritual community? To have such response rates of disagreement indicates perhaps a point to consider in program evaluation and one avenue of future research, focused on the construct of a spiritual educational community, since CIIS asserts that the integral education they offer "affirms spirituality" and that they are "committed to the study and practice of multiple spiritual traditions and to their expression and embodiment throughout all areas and activities of the Institute community" (CIIS, 2014a, para. 2). Furthermore, I would be curious to know more about how respondents applied their studies to daily life during them, and since graduating, if applicable.

Quantitative Phase: Open-ended Questions

After participants completed the scale, the inquiry then shifted to explore how each characterized an integral education, and to what degree they felt that earning an advanced degree in EWP influenced their personal and professional development. The objective here was to offer participants the space to articulate in their own words the nature of their experiences and understandings of earning a graduate degree in EWP. Table 8 shows a summary of the major themes from the open-ended responses, and seven or more occurrences constituted the item as a major theme.

Table 8: Summary of the Major Themes from the Open-ended Results

Question Details	Major Themes
In your view, what characterizes an Integral education?	Theme 1: Multiple Worldviews (13) Theme 2: Multidimensionality of Being (11) Theme 3: Multiple Ways of Knowing (10)
Please describe how your EWP learning experience and degree completion contributed to your personal development (If not applicable simply state that).	Theme 1: Expanded sense of self/Deepened Self-Understanding (23) Theme 2: Transformation/Development already in progress (7) Theme 3: Encouraged Exploration of Multiple Ways of Gaining Valid Knowledge (7)

Please describe how your EWP learning experience and degree completion contributed to your professional development (If not applicable simply state that).	Theme 1: Not Applicable (14) Theme 2: Academic/Scholarly (9) Theme 3: Indirect Effect (7)

Analysis of the survey data collected from the open-ended questions was most revealing. There were three themes that presented in the responses gathered regarding the initial question "in your view, what characterizes an integral education?" (1) multiple worldviews, (2) multidimensionality of being, and (3) multiple ways of knowing.

The first question is interesting because it does not directly inquire into the nature of the EWP program or CIIS per se, since it simply asks for the participant's view of how they characterize a particular educational method. Thus, one cannot assume that the responses are descriptors for the EWP department's educational offering. However, there was one participant who took it upon herself to add her thoughts concerning the lack of an integral education in the EWP program, stating "whatever it is I do not believe I received it in 2003."

At first glance, these themes generally correlate with the integral education espoused by CIIS today. Reflecting on the educational philosophy of the Institute, which affirms that the integral education at CIIS "encompass[es] all aspects of learning: the intellectual, the experiential and the applied" (CIIS, 2014b, para. 2), "values cultural diversity, multiple ways of knowing, spirituality, a sense of community… [and, by] exploring the interplay of mind, body, and spirit, integral education connects the spiritual and practical dimensions of intellectual life" (CIIS, 2014b, para. 3), the degree of correlation becomes more apparent.

At the time of this study, on the Institute's EWP website, the program's most up to date educational vision is reported as follows:

- To create a learning community focused on the exploration of Western, Eastern, and Indigenous psychologies and spiritualities in the spirit of integral inquiry and open-ended dialogue.
- To offer an integral education that honors not only intellectual excellence, but also the voice and wisdom of the somatic, vital, emotional, imaginal, and spiritual dimensions of the person.
- To bring spirituality into academia and explore the transformative elements of inquiry, learning, and writing.
- To foster the psycho-spiritual development of students, as well as their unique individual gifts and potentials. (CIIS, 2014d, para. 7)

Moreover, EWP today maintains that "through its unique combination of cognitive and experiential offerings, the department grounds academic excellence and the acquisition of professional skills in both the personal transformation of students and the cultivation of a spiritually informed scholarship" (CIIS, 2014a, para. 1).

Quantitative Phase Open-ended Questions: Personal and Professional Impact

The last two open-ended questions in Phase 1 of the present research sought to collect information about the personal and professional impact of participating in an integral education and earning a degree in EWP; this was intentional because the EWP department has historically offered a program that strives to nurture students ability to balance and integrate the many human dimensions, body, mind, spirit, alongside the development of professional skills, and a ground in practical application (see CIIS course catalogs from 1975-present). EWP's educational vision today maintains the heart of the original intent, and this study examined to what extent the vision holds true by collecting alumni perspectives of the personal and professional value they attribute to EWP since completing their advanced degree.

There were six themes present in participants' responses to the open-ended question, "Please describe how your EWP learning experience and degree completion contributed to your personal development (If not applicable simply state that)": (1) expanded sense of self/deepened self-understanding, (2) transformation/development already in progress, (3) encouraged exploration of multiple ways of gaining valid knowledge, (4) growth/maturation, (5) not applicable. The other open-ended question was similar, but professional is substituted for personal. "Please describe how your EWP learning experience and degree completion contributed to your professional development (If not applicable simply state that)"; there were five themes revealed as a result: (1) not applicable, (2) academic/scholarly, (3) indirect effect, (4) deepened current work, (5) one step on the path. Further analysis of each individual theme regarding participants' personal and professional development in light of the contemporary educational vision of the EWP department follows.

To summarize, the main characteristics of an integral education that were noted by participants were the honoring of the multidimensionality of being, or simultaneous development along multiple lines of intelligence, and the valuing of multiple ways of gaining valid knowledge. In regard to personal development, participants emphasized an expanded sense of self, and transformation in connection to their education in EWP. Professionally speaking, participants mostly reported no effect or an indirect effect, but others reported that their academic development while in pursuit of a Ph.D. was linked to their professional development post-graduation.

Qualitative Phase

In the second phase of the study, 10 of those who participated in the first phase volunteered their time for a qualitative interview. Each of the 10 interview transcripts revealed individual themes, and some overarching themes. There were 21 individual interview themes in total, and 11 overarching themes. As noted previously, Table 6 showed the major and minor overarching themes across the collection of interviews. The major themes were seeker/self-directed learner (10), positive aspects of EWP (7), takeaways (7), synchronistic unfolding (6), spiritual emergence/emergency (4), and critiques (4).

Participants used certain language to describe their experience, as if they were constantly engaged intentionally seeking out the next steps in their own psycho-spiritual unfolding. Thus, everyone interviewed showed characteristics of being a seeker/self-directed learner. Synchronistic unfolding and spiritual emergence/emergency also lend themselves to this major theme, since this type of descriptive language is only used by a certain kind of person, a seeker. Positive aspects of EWP, and takeaways shed light on what alumni perceive as the benefits of a course of study in EWP. Participants who shared the highlights of their time in EWP or spoke to what they gained personally and professionally from earning a degree in EWP fell into these categories. Interestingly, some of the major and minor themes are so related, they could be combined, and thus constitute another major theme. Specifically, critiques (4), what EWP lacked (2), no bridge (2) shadow side of spirituality (2), all indicate the learning edges of the EWP department. In other words, these themes could be a major theme, such as zone of proximal development, in which case, would have occurred 10 times in the second phase. However, in order to preserve the words of participants as best as possible, these minor themes were designated instead.

I would like to bring the reader's attention to the relationship between some of the themes. Specifically, both spiritual emergence/emergency and synchronistic unfolding could be a way to describe certain characteristics of the life of a seeker. Additionally, takeaways could be a more specific way to describe a positive aspect of EWP, and what EWP lacked could be a form of critique. No bridge, as well as shadow side of spirituality could also fit into the realm of critique. The point here is that the themes procured from the data collection are very much interrelated, and some could be cross-listed. They have been articulated as such in service of greater clarity and acknowledgement of certain participants' original wording.

The forthcoming paragraphs will focus on deepening the reader's understanding of the more ambiguous themes: positives of EWP, critiques of EWP, what EWP lacked, and takeaways. Note: some individuals offered more than one example of any given particular theme; this becomes evident when reflecting on the number of times the theme occurred across interviews and the number of specific responses below. Table 9 shows the distinctness of responses concerning each of the aforementioned themes.

Table 9: Distinctness of Participant Experience Regarding Ambiguous Themes

Theme	***Specific Responses***
Positive Aspects of EWP (7)	(a) EWP 7793 *East-West Spiritual Counseling Skills* (b) grateful for the learning experience (c) newfound curiosity for the field of Psychology (d) concentrated inner work (e) soul work "I'm a more congruent person…we've all grown immeasurably" (f) professional/academic preparation (g) development of critical thinking skills (h) development of analytical thinking skills (i) 500 hours of internship (j) receptive (k) non-judgmental (l) freedom/flexibility to co-create one's curriculum (2) (m) faculty support (n) nurturance of each individual student's psycho-spiritual unfolding (o) EWP 6150 Eastern Theories of Self, Mind, and Nature (3) (p) opportunity to be a spiritual innovator

	(q) constant challenge of engaging with a community of scholars (r) full support from faculty mentors to follow passion/curiosity
Critiques (4)	(a) expected professional development/preparation; not delivered (b) inappropriateness of some faculty members (c) unsupported, concentrated form of inner work (d) anti-intellectual climate (e) systematic and detailed approach to spirituality not present (f) dogmatization of specialty (g) the dept. killed the dream of Dr. Chaudhuri (h) allegiance to Sri Aurobindo and the Mother was marketed, yet not practiced/delivered (i) privileged/entitled student body (2) (j) hefty student loan debt (k) indefinable degree
What EWP Lacked	(a) lack of connection and applicability of studies to social issues (b) strong sense of community not present (2) (c) race/gender/class/social justice issues absent from the curriculum (d) professional development (2) (e) community/interpersonal support (f) more grounded approach to inner work and psycho-spiritual Development

Looking at the myriad of responses under each theme exposes a wealth of information regarding to what degree student learning outcomes match up with the educational vision set forth by CIIS and the EWP department. Student satisfaction levels were also indicated in the data collected, both in the sense of positive aspects of the program and what students report they are taking away from their time studying in EWP, as well as regarding more critical feedback and when students attest to feeling dissatisfied. Interestingly, one participant noted the professional and academic preparation in a positive light, and two others noted that was one aspect that was lacking in EWP. Sense can be made of this divergent perspective if one refers back to the CIIS course catalog literature from 1975-present. The participant who reported strong professional and academic preparation was an alumna of the EWP program back in the 1980s, whereas the two participants who mentioned this was an area of lack with EWP had been more recent, having graduated in the last five years. I would be curious to further explore the distinct iterations of EWP through alumni experience, using the course catalogs as a way to guide the organization of the sample. Also interesting to note is the evidence of correlation between the phases of research.

In the first phase of the study, 49% participants reported a deepened sense of self/expanded self-understanding when asked about their personal development in correlation to their EWP educational experience in the open-ended response data. The second phase also presented evidence of expanded self-understanding is present in the transcript data, and this was expressed in some of the responses categorized as takeaways. For example, interview participants reported increased somatic and emotional awareness, deepened self-understanding and self-knowledge, expanded awareness of shadow and increased integration capacity, as well as stronger sense of identity and passion as takeaways from their EWP educational experience. These examples warrant more exploration to be determined as qualities of deepened self-understanding, and they could prove useful in guiding future lines of inquiry.

The responses coded as "what EWP lacked," the “critiques,” as well as "no bridge," and "shadow side of spirituality in education" were less present in the first phase of the research. However, interview participants did mention the lack of professional development, and two more reflected on the lack of a bridge from studying at CIIS to transitioning into meaningful contributor to society. These interview responses were akin to the most prevalent response regarding the open-ended question which inquired into the nature of alumni professional development and its connection to their course of study and degree completion in EWP; 30% (N = 14) reported "not applicable."

Findings Summary and Conclusion

Considering all the responses from both phases, there is evidence of some correlation. The major themes revealed from the open-ended questions were validated in some ways through the qualitative interviews. Specifically, participants' responses in regard to personal and professional development in the first phase were shown in more detail in the second phase. For example, the most prevalent theme in the second phase, seeker/self-directed learner, was also present in the open-ended responses in regard to personal development. When asked about their EWP education and its connection to personal development, seven reported that their transformation and/or development was already in progress and would be a quality of their lives, whether they studied in EWP at CIIS or not. Both phases thus offer some information concerning the character, or personality of the students who decide to enroll and complete a graduate degree in EWP.

Overall the results of this mixed-method study point to the areas where the EWP program is doing well in terms of what students expect and what they actually get, and also to the areas that could use improvement if the department was to offer an education that better reflects the ideals of the Institute, as espoused by the program description and advertisement. The most significant findings are the revelations of the need for (a) more professional development for students completing a degree in EWP, (b) more practical application opportunities, for example, internships, teaching assistantships, scholarships, fellowships, and connection of studies to social and global issues, (c) more community/mentor support for students' personal psycho-spiritual unfolding, and (d) more training regarding the language and articulation needed to communicate the value of an integral education effectively with scholars/employers outside of CIIS.

There was also evidence in both phases that EWP is offering an educational experience that honors (a) multiple worldviews and perspectives, (b) the multidimensionality of experience, for example, physical, emotional, mental/intellectual, spiritual, relational, and (c) multiple ways of gaining valid knowledge, not just through the mind. Participants also reported across phases that they experienced (a) an expanded sense of self, (b) deepened self-awareness and/or knowledge, and (c) a new ability to hold multiple perspectives, even those contradictory to their own. Thus, there is evidence indicating that what CIIS aspires to is actualized according to some alumni reports.

The findings of this mixed methods study reveal perhaps more questions than answers; however, they are relevant to the EWP program, CIIS, and the field of higher education assessment research in general. Alumni perspectives on the personal and professional value of earning a non-traditional graduate degree helped to articulate what the Institute does well in regard to the practice of integral education, what could be better implemented, and where the Institute could grow. These findings suggest best practices, critical reflections, as well as recommendations to improve the integral education model in practice at CIIS, thus inviting further refinement of the practice of integral education, and movement towards greater alignment with the educational values CIIS strives to uphold.

APPENDIX A
SURVEY QUESTIONS – TRANSFORMATION EVALUATION SCALE

Thank you for your willingness to participate in this research project exploring your educational experience in the East-West Psychology Program. Please read each of the following statements carefully. Reflect on your overall EWP experience as you consider each statement and then, using the following rating scale, please choose one of the five options listed below.

(5) Strongly agree
(4) Agree
(3) Neither agree nor disagree
(2) Disagree
(1) Strongly Disagree

1. Throughout the program, in general, I felt emotionally supported during class time.

2. My education in EWP helped me develop an expanded sense of self.

3. Learning about psycho-spiritual disciplines inspired me to develop a personal, regular self care practice.

4. The education I received from EWP helped me develop new levels of emotional maturity.

5. As a result of my education in EWP I was taught to honor multiple ways of knowing.

6. I became more mindful as a result of my education in EWP.

7. I learned how to experience embodied knowing as a result of my education in EWP.

8. I was challenged to become aware of and reassess my worldview assumptions through my EWP education.

9. My education in EWP awakened in me a sense of global citizenship and responsibility.

10. EWP offered me an Integral Education.

11. What I learned in the EWP program catalyzed a significant change in my lifestyle.

12. As an alum I still feel I am part of the EWP community.

13. My education in EWP helped me become more aware of the underdeveloped aspects of my personality.

14. As a result of my EWP education, my ability for authentic self-expression improved.

15. My EWP education has been indispensible to my professional development.

16. My education in EWP has helped me actualize my higher potentials.

17. My education in EWP fostered the development of interpersonal communication skills.

18. My EWP education made it possible to relate to all beings more authentically.

19. Through my education in EWP I learned to respect worldviews contradictory to my own.

20. The people I met during the program were instrumental to my growth.

21. My EWP education catalyzed a significant change in the way I relate to others.

22. My education in EWP taught me how to support others in their psycho-spiritual transformation process.

23. My EWP education had a noticeable positive effect on the quality of my relationships.

24. My education in the EWP program increased my capacity for genuine intimacy.

25. Being emotionally supported while completing my degree contributed to my spiritual/transpersonal development.

26. My relationship with the sacred (however you define that) deepened throughout the program.

27. While in the program, I felt part of a spiritual community.

28. EWP helped me develop a regular spiritual discipline.

29. As a result of my education in EWP, I am more mindful of my impact on the environment.

30. Being a part of EWP, I became part of a community which honors multiple worldviews.

31. My EWP education engaged the various aspects of my being.

32. The EWP program catalyzed a significant change in the way I relate to the world.

33. My education in EWP taught me to honor the multidimensionality of existence

34. Since completing my degree in EWP, my sense of self has expanded, allowing for more authentic spiritual expression.

35. My education in EWP has inspired me to experience life as an ever-unfolding evolution of consciousness.

36. Since completing my degree in EWP, I embrace an integral worldview.

37. As a result of my education, I actively seek opportunities to grow spiritually.

38. The education I received from EWP has helped me access greater understanding of my intuition.

39. In my experience, EWP fostered my psycho-spiritual transformation.

40. In retrospect, I had a positive experience of EWP overall.

The following three questions are open-ended

41. In your view, what characterizes integral education?

42. How has your EWP learning experience and degree completion contributed to your personal development?

43. How has your EWP learning and degree completion contributed to your professional development and current pursuits?

Women's Spirituality at CIIS: Uniting Integral and Feminist Pedagogies

Alka Arora[1]

Abstract: This paper articulates an educational framework termed integral feminist pedagogy, based on the author's experience teaching in the Women's Spirituality program at the California Institute of Integral Studies. Integral feminist pedagogy unites the principles and practices of both the integral and feminist traditions. The strength of integral pedagogy lies in its focus on the inseparability of an individual's mind, body, and spirit. However, integral pedagogy is often understood today in a way that divorces individuals from their social and political context. Feminist pedagogy, on the other hand, excels in raising students' awareness of social and political context, but may neglect individuals' psychospiritual realities. This paper argues that integrating the two traditions helps each better fulfill its vision of social transformation. In order to illuminate the core premises of integral feminist pedagogy, specific examples from classrooms in the Women's Spirituality program are explored.

Keywords: Integral education, diversity, feminism, social justice, spirituality.

> *Education at its best—these profound human transactions called knowing, teaching, and learning—are not just about information, and they're not just about getting jobs. They are about healing. They are about wholeness. They are about empowerment, liberation, transcendence. They are about reclaiming the vitality of life.* Parker Palmer (1997, p.3)

Introduction

How do we as educators hold our students as whole, embodied beings navigating a world of immense oppression but also of immense beauty? How do we engage them in thinking critically about power and privilege while also honoring and encouraging their self-expression and personal growth? How do we foster both "liberation," and "transcendence," as Palmer (1997) suggests the best education can do?

In this paper I attempt to answer these questions by articulating a model of integral feminist pedagogy that is based on my experience teaching in the Women's Spirituality program at the

---

[1] Alka Arora, PhD, is core faculty member and former director of the Women's Spirituality Program at the California Institute of Integral Studies. She holds a PhD in Women Studies from the University of Washington, where her dissertation examined spiritual discourses among third-wave feminists in Seattle. Her teaching interests focus on multicultural feminist spirituality, integral pedagogy, and animal rights. Some of the courses that Alka teaches include "Spiritual Activism and Transformative Social Change," "Liberation Dharma: Gender, Buddhism, and Social Justice," and "Sacred Lineages: Goddesses, Foremothers, and Activists." She is currently doing research for a co-authored book on feminist spiritual activism.

California Institute of Integral Studies (CIIS). This model marries two distinct pedagogical traditions that have each profoundly shaped my educational philosophy and practice. The integral tradition emphasizes the interrelatedness of mind, body, and spirit; feminist education, meanwhile, focuses on the connection between the personal and the political. To bring them together is to recognize that our “selves” – our minds, bodies, and spirits – are embedded within a system of social and political relations. We are multidimensional beings, possessing both interior depth and social breadth. An integral feminist pedagogy can engage students on these multiple levels at once, and thus provide a deeper level of transformation than is possible via either tradition alone.

I enter this conversation as a woman of color educator who has been teaching at the university level for seventeen years. I began my university teaching career as a graduate student at the University of Washington (UW), where I worked with undergraduate students in Women Studies classrooms. My experience of feminist education at the UW, as both a student and instructor, was powerful. The breadth and nuance of feminist politics came alive for me in these classrooms. However, I also experienced an internal dissonance as my spiritual self was left out of the discussions. I longed for a place to talk about my inner, spiritual life and how it was being influenced by what I was learning politically. In every class that I taught, I noticed at least a few students who seemed to share a similar longing.

Coming to teach at CIIS thus felt like a breath of fresh air. Finally, it seemed, I could be my “whole self” and find a welcoming space for the discussion of intuitions, dreams, encounters with the sacred, or intrapsychic realities. However, I soon came to see that many spaces at CIIS were absent of discussion of political structures and of gendered and racialized experiences, despite the founder’s vision of spiritual and social integration. My “whole self” was not welcome, after all. Many CIIS students (and faculty) tended to gravitate toward either spiritual or political realms, reproducing the dichotomy found in the culture at large. While my own program, Women’s Spirituality, explicitly strove to challenge this dichotomy, we had to do so against the grain of cultural conditioning that views spiritual and political liberation as wholly separate.

Despite the challenges, I believe that the Women’s Spirituality program has been able to offer a uniquely transformative education by consciously bridging the spiritual and political. As core faculty in the program, I have had the opportunity to reflect deeply upon how to interweave the two realms in the classroom. My articulation of integral feminist pedagogy is grounded in some of these everyday classroom experiences.

In the following sections, I examine the histories and core tenets of both integral pedagogy and feminist pedagogy. I then reflect upon the history and evolution of the Women’s Spirituality program at CIIS, highlighting the pedagogical challenges and opportunities the program has faced. In the final section, I share four core premises of the integral feminist pedagogical model I use in my own teaching.

Integral Pedagogy

At the very heart of integral pedagogy is the belief that education should engage not just the intellect, but also the inner dimensions of the person such that deeper levels of learning and transformation are made possible. While the tradition of integral education is rooted in the works of multiple philosophers, including Rudolf Steiner, Jean Gebser, and Ken Wilber (Esbjörn-Hargens, S., Reams, J., & Gunnlaugson, O., 2010) it is the work of Sri Aurobindo as explicated and implemented by Haridas Chaudhuri that has been so pivotal to the development of CIIS and of my own understanding of integral pedagogy.

Born in 1872 in British-controlled India, Aurobindo came of age at a time when rote, mechanical education was the norm. His belief that learning should be centered on the student, while commonplace today was radical for his time (Subbiondo, 2005, p. 20). In many ways, his focus on liberating students to discover their own truths prefigured the work of Paolo Freire (2008), whose critique of the “banking” model of education has had global influence.

Aurobindo, well ahead of his time, also advocated ideas that would later be associated with movements such as feminism and postmodernism. For instance, he asserted a belief in multiple truths and multiple ways of knowing. According to Reams (2010), Aurobindo valued "an integration of what were previously considered as paradoxes, a capacity to see previously disparate perspectives as interconnected" (p. 8). Unlike most of today’s postmodern thinkers, however, for Aurobindo these truths went beyond socially-constructed perspectives to also include the truths of the body and the spirit.

Integral education, sparked by Aurobindo’s philosophy, has from its outset recognized and honored the spiritual dimensions of the individual. It is based on the belief that “there is a mode of consciousness available to us that is qualitatively different from our common, ordinary, rational, everyday consciousness” (Reams, 2010, p. 8). By accessing this mode of consciousness—through meditation, art, or reflective writing, for instance—students and faculty tap into another source of knowledge that complements and enriches academic learning. Teachers who use integral methods might, for instance, interweave scholarly analysis with contemplative reflection; lectures with movement practices; or classroom discussion with sacred ritual. Such integrative practices support students’ capacity for deeper learning and transformation.

Aurobindo's emphasis on an individual's potential for transformation did not negate the importance of our social worlds. As Wexler (2005) notes, "since the nondualistic view [of integral philosophy] did not separate the Divine from the material world, there was also an emphasis on action in this world as an expression of our inherent spiritual nature” (p. 31). Indeed, Aurobindo's integral philosophy included a belief in cultural evolution driven by psychologically and spiritually mature persons who would herald a new, harmonious society.

As I mentioned above, numerous other thinkers have taken up the concept of “integral” education since Aurobindo’s time. While the integral tradition has become vast, I would like to summarize here what I see as the core practices of integral educators, who strive to:

- Create spaces where the numinous dimension of existence can be explored without forwarding any particular religious or philosophical dogma.
- Engage students’ inner lives in a way that supports their psychological and spiritual drive toward wholeness.
- Embrace multiplicity, paradox, and uncertainty while encouraging their students to do the same.

- Foster hope in the possibility of both individual and social transformation.
- Provide tools for students to explore deeper questions about the meaning and purpose of their lives.

Notably, this list includes an emphasis on the cultivation of social as well as individual growth. Indeed, Aurobindo was an anti-colonial revolutionary who fought for India's independence from British rule. His teachings were not apolitical. However, as they made their way to the US, integral ideas became practiced in a way that has generally privileged an individualistic perspective over a collective one. This stems in large part from the relatively privileged social status of early adopters of this framework, as well as the individualism inherent in Western capitalist society. It also derives from the fact that integral education was taken up with great zest by psychologists, who are primarily trained to look at individuals in the context of their family and interpersonal dynamics, rather than at macro-systems. Wexler (2005), Academic Vice President at CIIS, has acknowledged this danger in integral education:

> Another risk is that the emphasis on the personal may create the illusion that everything is personal and individual, with little recognition given to the impact of society, social roles, or power dynamics. Thus, for example, the discussion of diversity in this environment faces particular challenges related to the emphasis on personal development. We hear white students talk of their spiritual work as having enabled them “to move past diversity” without recognizing the cultural and social constraints that make such transformation impossible in terms of life in contemporary society. (p. 32)

Wexler's comment affirms my own experience with students at CIIS, particularly those from privileged racial or class backgrounds. Given the tendency toward privatized notions of psycho-spiritual growth in the West, I assert that educators must actively bring in a social and political analysis to remain true to the vision of integral pedagogy. The insights and strategies emerging from feminist pedagogy can be invaluable here, and I turn now to an overview of this tradition.

Feminist Pedagogy

In contrast to the self-focused idea of “transformation” that is espoused in many integral classrooms, the feminist pedagogical vision is one of widespread social transformation. Such transformation involves a restructuring of the relationship between the genders, at minimum; more and more feminist educators today hold a wider vision that involves a radical transformation of gender, sexuality, race, our economic system, and relationship to the earth. Feminist educators view the classroom as a site where students can become critical thinkers who question the status-quo and who develop deeper insights about social and political relations. With an expanded understanding of the world and their place in it, students can develop the necessary agency to change it.

The history of feminist pedagogy is rooted in the women’s liberation movement of the 1960s and 1970s. While women were entering the halls of higher education in ever-increasing numbers, they realized that the content they were learning continued to be developed and taught by men – predominantly white men. Examining higher education curricula of that era, feminists “observed that sometimes women were missing altogether, sometimes women appeared only in images that reflected men's perspectives, and sometimes women's activities and everything considered feminine were devalued" (Boxer, 1998, p. 52).

Feminists developed alternative sites of knowledge production, coming together in "consciousness raising" groups where they discussed their experiences of sexism and developed shared analyses of patriarchal oppression. These leaderless groups, where women sat in a circle to share their lived experiences, came to emblemize feminist education and greatly influenced the structure of women's studies classes. Podiums and formal lectures were supplanted by students sitting face to face, engaging with each other and with course texts in a dialogical manner. The teacher's role morphed from "expert" to guide and facilitator; students were invited to view themselves as co-creators of knowledge (Boxer, 1998; Fisher, 2001).

Feminist pedagogy evolved in conversation with critical pedagogy, a tradition based in a critique of capitalist power relations. Critical pedagogy challenges the class based inequalities that have been perpetuated through mainstream education. Paulo Freire is widely considered the father of critical pedagogy; here, Shaull (2000) summarizes Freire's perspective on education:

> Education [for Freire] either functions as an instrument which is used to facilitate integration of the younger generation into the logic of the present system and bring about conformity to it, or it becomes "the practice of freedom," the means by which men and women deal critically and creatively with reality and discover how to participate in the transformation of their world. (p. 34)

The critical tradition brought to feminist pedagogy an expanded focus on class and political economy. Meanwhile, feminists of color stressed the importance of racialized power relations, and helped move feminist pedagogy away from universalizing women's experiences.

All of these influences helped bolster the feminist insight that that one's social location and access to power profoundly shape what one knows and how one sees the world. Feminist educators challenge the concept of academic "objectivity," "see[ing] it instead as a mask for bias" (Boxer, 1998, p. 73). Suspicious of androcentric and Eurocentric biases in scholarship, feminist teachers seek to uncover the stories and realities of women, people of color, and others who have been marginalized or oppressed.

As issues of race, class, and sexuality came more to the fore in feminist classrooms, female students could no longer see themselves as simply targets of patriarchal oppression. White, middle-class, and heterosexual students had to reckon with their privilege in a complex system of power-laden identities. The feminist educators' job, then, became not only one of empowering women students but also of challenging them to recognize their privileges.

Even as feminist pedagogy has evolved over time, what remains distinctive about it is its recognition that matters previously considered purely "personal," are, in fact, collective and political concerns:

> Topics that had been considered strictly "personal," such as how a woman felt about her body, how sexual violence or sexual pleasure affected her, the consequences of marrying and having

children, what it meant to become educated, how to deal with problems at work, at home or outside it, all became the focus of intense discussion [in consciousness raising groups, and later in feminist classrooms]. (Fisher, 2001, 29)

Such "personal" concerns become a central focus point for feminist organizing because they reveal broad social patterns such as gender-based violence, economic inequities, and limiting gender roles. The first-person narratives of women help illuminate systematic and institutionalized imbalance of power structured by gender, race, and class. Historical and political context is integrated with narratives of lived experience to develop feminist theory and praxis.

To sum, feminist educators:

- Believe that education can and should inspire social transformation and the undoing of patriarchal systems.
- Engage students in historically situated analyses of power and privilege.
- Embrace narratives of personal experiences as sources of knowledge and alliance building.
- Support students in unlearning internalized oppression and internalized privilege.

Like integral educators, feminist teachers ask students to bring their whole selves into the classroom—but this "whole self" is understood not as "mind/body/spirit" but rather as a socially and politically situated self. Whereas the integral educator's goal may be to examine patterns in the human psyche or in spiritual experience, the feminist educator's is to do so in the context of social and political patterns.

However, in my view, feminist pedagogy in the secular academy has suffered from being steeped so deeply in a materialist analysis of oppression that the numinous dimensions of life have been marginalized. Helen LaKelly Hunt (2004) points out the irony that many feminist sites that welcome discussion about some of the most intimate aspects of our lives—sexuality, for instance—still consider spirituality a taboo topic. Thus, while inviting students to bring their embodied experiences into the classroom while negating their spirits, feminist educators may inadvertently reproduce the split between the "private" and the "political" that they decry. Bringing an integral lens to bear on feminist education can, therefore, help feminist pedagogy better fulfill its vision.

Women's Spirituality at CIIS

While women's spiritual experiences remained marginal to feminist discourse at large, they were centered in the emerging women's spirituality movement of the 1980s. Spiritual feminism grew out of the same mix of consciousness-raising and political activism that motivated secular feminisms. But while many secular feminists adopted the Marxist view of religion as simply the "opiate of the masses," spiritual feminists looked deeper. They agreed with secular feminists that patriarchal religions upheld women's oppression. However, rather than casting out religion altogether, spiritual feminists insisted that the spiritual impulse preceded patriarchy, and that the practice of woman-affirming spirituality held the key to transforming it.

The Women’s Spirituality program at CIIS, founded in 1992, grew out of this women’s spirituality movement. Scholars and practitioners took the feminist query “what happens when women ask the questions?” (Boxer, 1998, title page) to the realms of religion and spirituality. What they found was that the world’s historical religions have been preponderantly developed for and by men, and specifically the elite men of any given society. Moreover, these religions have sustained the structural oppression of women and as well as women’s own internalized oppression.

Many of these scholars focused on uncovering suppressed knowledge about ancient Goddess and mother-centered societies around the world. Others reclaimed female spiritual leaders and woman-affirming teachings within the existing traditions. Regardless of their approach, what united them was the conviction that transforming symbol systems and religious worldviews were key to women’s liberation.

Pedagogically, Women’s Spirituality at CIIS shared with women’s studies a focus on linking the personal and political, bolstering women’s agency, and transforming androcentric curricula. However, the focus on interior, spiritual experiences made this program distinct from women’s studies programs and is why it found a home at CIIS. Though Women’s Spirituality had different intellectual roots than the integral tradition, both shared the belief in the interrelatedness of mind, body, and spirit.

Students in our program have been supported in excavating their own relationships to patriarchal symbols and tropes, and in exploring an alternative, embodied, and relational sense of the female Divine. At the same time, they have increasingly been challenged to analyze the complex social and political systems that affect the concrete lived experiences of women—and of all genders—today.

Integrating these two modes—the spiritual and the political—has been a creative challenge. Even as faculty in the program strive to break down the binary between the two, we are embedded within a wider discursive terrain where the spiritual and political are split. The texts we rely upon often stress one domain over the other, as do many of our academic associations. Given this cultural splitting, it is perhaps unsurprising that different students come to the program with interests more strongly in one realm or the other. Some of our students have expressed a desire to study women’s spirituality without having to study feminism, unaware how the two have always been intertwined. Others, meanwhile, have been drawn to us primarily because of our focus on social justice, and enter the spiritual discourse more tentatively.

In addition, the program itself has gone through a significant evolution over the years. The original program was focused more on women recovering their agency as those who had been oppressed through patriarchy. Primarily Euro-American, these women held significant racial and class privilege despite having experienced significant sexism in their lives; such privilege allowed them to focus primarily on healing from oppression. As more working-class women and women of color joined the program, the recognition that women, far from being innocent victims of an undifferentiated patriarchy, also colluded in the oppression of other women, came to the fore. Thus, finding ways to raise students’ awareness of their own privilege or oppressive attitudes became increasingly important.

Meeting these pedagogical challenges has led me to reflect on how to best integrate the interior and psycho-spiritual dimension of integral teaching with the relational and political dimension of feminist teaching. By uniting these two traditions, we can foster deeper transformation than is possible with either alone. In the following section, I outline some of the core premises of this integral feminist pedagogy.

Integral Feminist Pedagogy

The first premise of integral feminist pedagogy is that both educators and learners are multidimensional beings who must be engaged as both spiritual and political agents. As feminist and critical perspectives have demonstrated, we are each situated within specific social, historical, and political locations that shape our experiences and our standpoints. However, an integral feminist perspective suggests that we are each also situated within a specific metaphysical worldview that both reflects our sociopolitical location and shapes how we respond to it. In this view, even atheism has its own set of metaphysical presuppositions and is culturally and historically specific.

In the Women's Spirituality program, for instance, we discuss how exclusively or predominantly male images of the Divine have helped create a social system that privileges male experience. We also examine how spiritual practices that help individuals tap into their own inner wisdom may support liberation from patriarchal conditioning and authority. In some classes, we might explore differing beliefs on how metaphysical tools such as prayer or ritual might influence material reality and social conditions.

This engagement with students as spiritual and political beings leads to my second premise, which is that social justice education must address students' inner worlds. Coming into consciousness about systems of oppression brings with it a multitude of emotions as well as deep questions. Students' grief, anger, and shame about the violence and oppression in our world often lead to questions about meaning and purpose. For instance, they may strive to make meaning of collective suffering and reflect on their desires to be agents of change. Some students wonder what they can believe in when they came to realize that so much of what they have been taught is based in oppressive ideologies. By providing a space in which students can have an open dialogue about these types of questions, educators can help foster students' ability to access their own inner wisdom as they struggle to make meaning.

The third premise of an integral feminist pedagogy is that psychospiritual maturity requires one to awaken to issues of oppression and injustice. Esborn-Hargens et al. (2010) note that integral education includes "shadow work". They write:

> We also have learned the importance of students and teachers become more self-reflective and increasingly aware of their trigger points - what makes us reactive, dismissive, or shut down to ideas and other people. By learning to look at what we do not want to see in ourselves (and others) we become more compassionate and open to learning. This is an ongoing process of owning our projections, minimizing idealization, avoiding the tendency to split things into good and bad, catching ourselves when we are rationalizing away our responsibility and so forth. (p. 6)

Much of the discussion of shadow work in this type of literature focuses on our projections within interpersonal relationships; while valuable, this literature has yet to attend to the role of relationships of oppression and dominance that also comprise our “shadows.” By creating a space wherein students can openly explore how systemic oppression has become steeped in all our psyches, we can develop non-shaming ways of decolonizing attitudes.

A specific example from one of my classes can help illuminate this point. I teach a course titled Building Conscious Allyship, which introduces students to a broad scope of social justice issues in a way designed to build empathy, reflection, and the desire to foster change. While the content of the class is primarily on understanding how oppressions from racism to ableism operate on both macro and micro levels, the process involves deep inquiry work and dialogue. At the end of the term, a thirtysomething year old white student, whom I'll call Jennifer, wrote the following:

> So, my own internalized shame story about being white in a racist society can be an entry point for consciousness, or, without awareness, it can serve to generate reactions that numb me into reproducing the very conditions that create the feeling ... What one discovers about consciousness, however, is it’s not just the bright light shining; the light reveals all that has heretofore been concealed. The shadows. The unseen. The pushed away. In our desire to be allies to one another, we will invariably and inevitably butt up against those places in ourselves (be it our privilege, our complicity, our own victimization, our silence, our betrayals of self and other, etc.) that we might rather not meet. (unpublished manuscript, n.d.)

She continues with a reflection on how her spiritual life necessitates the work of unlearning oppression:

> If my primary spiritual task includes remembering myself as whole, divine, and holy, and thus to re-member (bring into the body and into membership/ community) the divine Source in all beings, then it is also my task to explore where (and how and why) I am resisting that truth through participation (unconscious as well as conscious) in and the recreation of structures that oppress anyone or anything in my name. (unpublished manuscript, n.d.)

As Jennifer's reflections so beautifully capture, psychospiritual transformation and social transformation are not separate spheres; they can be one and the same. By refusing to privilege politics over inner spiritual work, or vice versa, integral feminist educators can facilitate students' processes of making their own connections between these entwined dimensions.

The fourth premise of my integral feminist model, which follows from the first three, is that we must understand the human drive toward healing and wholeness as a collective rather than purely private endeavor. When understood in collective terms, healing and wholeness are no different than justice and liberation. As Cornel West has famously stated “justice is what love looks like in public.” Too often, students are asked to engage issues of oppression in a disembodied, academic way that leaves little room for the creativity of their spirits. When we open up the possibility for them to see that their own spiritual well-being is intricately tied to the well-being of all, West's statement becomes an embodied truth.

Conclusion

This paper put forth a vision of an integral feminist pedagogy that interweaves the best practices of integral pedagogy with those of feminist pedagogy. The histories of both traditions reveal a focus on multiple truths, embodied experience, and social transformation. However, the integral tradition as understood in the contemporary West has too often been apolitical, while the feminist tradition has been “aspiritual.” In the Women’s Spirituality program at CIIS, we challenge the split between the political and spiritual and we encourage students to recognize how the two realms have always had mutual influence. Based on my experience teaching in this program, I articulate four key pedagogical premises of an integral feminist paradigm. I contend that this paradigm can support a process of deep psycho-spiritual and political transformation.

The Divine Feminist: A Diversity of Perspectives That Honor Our Mothers' Gardens by Integrating Spirituality and Social Justice

Arisika Razak[1]

Abstract: While spirituality has often been separated from feminism, this essay suggests that a number of prominent theorists in the diverse fields of Africana Studies (Amadiume, 1998; Badjo,1996; Teish,1994); Chicano Studies (Anzaldua, 2007/1987); Indigenous Studies (Harjo, 1991; Mehesuah, 2003); Islamic Studies (Wadud, 2006); Queer Studies (Grahn, 2009); and Women's Spirituality/Women and Gender Studies (Brooten, 2010; Walker, 1983) have all linked empowered roles for women and other oppressed groups to contemporary and historic liberatory spiritual frameworks and culturally specific Indigenous roles for women and other oppressed genders. The contemporary *divine feminist,* (a term coined by Professor Alka Arora) is one who walks the contested borderlands between secular feminisms, philosophy and religious studies, and ethnic/indigenous studies. They integrate diverse spiritual frameworks elaborated by people of color, liberatory theory and praxis supporting the empowerment of women and other oppressed genders with Euro-American academic perspectives, and contemporary disability and embodiment studies to develop new forms of activism, scholarship and alliance building that benefits the Earth and all sentient life.

Keywords: African Diasporic Spiritualities, African women, Alice Walker, Amina Wadud, borderlands frameworks, divine feminine; divine feminist, Gloria Anzaldua, Indigenous Studies, Luisah Teish, *nepantiera,* Oshun, Women's Studies, womanism, Women's Spirituality.

I begin by honoring "our mothers' gardens," a phrase taken from the essay, *In Search of Our Mothers Gardens* by Alice Walker (1983). In her essay, Walker honored the many poor and working class Black women who were denied the time and leisure to create what the Western world deems as 'art' – but whose work in designing quilts, making songs, or growing large "ambitious (flower) gardens" (p. 241) reflected their need to create beauty and art *regardless* of their circumstances. Her loving tribute to those who came before her reflects indigenous protocols of respect, which are embedded in many traditional spiritual practices of Africa and the Americas.

In these traditions, before any ceremony begins, the human community must acknowledge those who came before us, on whose shoulders we stand. In many holistic, embodied indigenous religions, those whom the West designates as 'human beings' include the dead, the living, and the yet to be born. They include those who have recently died, the older yet still remembered ancestors, and those ancestors born so long ago that they are seen as spiritual entities, who stand as intermediaries between human life and the primal powers of the universe. These primal powers include elemental forces of wind, water, earth, fire, metal and air. They include the life-giving and life guiding presences of the sun, the moon, the mountains, and the stars. They include rivers, deserts, oceans and streams as well as herbs, plants, and forests. Finally, they include the spirits that animate all our human and non-human kin and the deities who preside over the entire web of life—those who have guided the life and work of our ancestors in the past, who continue to inform the life and work of our kin today, and who will – Spirit willing – continue to inform the lives of our children, grandchildren and great grandchildren.

Following this tradition, I begin by acknowledging the many artists, activists, teachers, and scholars who have not only contributed to my thinking, but who have made the world a better place through their thinking, their courage, their generosity and their work. Some of the women I wish to acknowledge are established scholars, whose written works are published and well known. Others, less well known, are community activists, healers, and religious practitioners. Some, nameless, and unknown, are mothers, community mothers, other-mothers[2] and elders. They include the unknown ancestors who endured the unspeakable, in hopes that life would be better for the children. I am their descendant and I honor them with a poem by Luisah Teish[3] entitled "Mother of the Night."

I am the Mother of the Night.
The Great Dark Depth, the Bringer of Light.
All that was, that is, that ever shall be,
All that could or should can only come from me.
High above and far below. I am the ebb, I am the flow. The
    stars in the sky, the fish in the sea. Every seed, every
    stone, every critter is me.
I am the Center, the Beginning the End. I am without and
    I am within. I am the lair, the nest and the den. I am
    the Earth, the Water and Wind.
The Horned Cow, the many-teated Sow, the Queen bee,
    the Mothertree, the Pregnant Womb, the Grain-seed

---

[2] This term arises out of the African American notions of extended family and *fictive kin* which recognize biological motherhood as well as extended "family" relatives who take in, care for, and shelter the young of the community when their own parents are unable or unwilling to do so. While they may be called "mother" "aunt," "uncle," "cousin," etc. *fictive kin* may or may not be related by blood; sometimes they are related only by ties of affection. See Collins, P.H. (2000). *Black feminist thought: Knowledge, consciousness, and the Politics of Empowerment* (2nd Ed.) New York: Routledge, pp. 179-183.

[3] Luisah Teish, Woman Chief, initiated elder and *Iyanifa*, is an internationally known scholar and healer. Her works include: Teish, L. (1985). *Jambalaya: The natural woman's book of personal charms and practical rituals.* New York: HarperCollins. Teish, L. (1994). *Carnival of the spirit: Seasonal celebrations and rites of passage.* New York: HarperSanFrancisco.

broom, the candle's wick, the Matrix, and woman,
you are my daughter.
Praise and Love to the Mothers of the World.
Praise and Love to the Sisters of the World.
Praise and Love to the Women of the World.
Praise and Love to my daughters.
To the women in the fields, who plow and plant and turn
mill wheels. To those who spin and weave at looms
who make the mats, the cloth and brooms. To those
who sew the royal robes, to those who pierce the
child's earlobes. To those who rub and oil and braid.
To all the Queens and all the Maids.
Praise and Love to my daughters.
To those who nurse babes on their breasts, who carry on
without due rest. Then rise up early as the dawn to
mend the fence and mow the lawn. To those who mix
and stir the pot, to those who bake and clean and
mop, to those who have and   who have not.
Praise and Love to my daughters.
Praise and Love to those who seek, to those who know and
those who speak. To those who smile with tender eyes,
whose wisdom penetrates the lies. To those who sing
and those who cry. For those who fight for right and
die! To those who live to ripe old age, to great-grandma
the family sage. Praise and Love to my daughters.
To those unborn and yet to come, we bid you on with
song and hum. From other worlds and through birth
water. Come forth child, beloved daughter.
Praise and Love to the Mothers of the World.
Praise and Love to the Sisters of the World.
Praise and Love to the Women of the World.
Praise and Love to my daughters. (Teish, 1994, pp. 22-23)

In this poem, Luisah Teish who is an initiated elder, an *Iyanifa*[4] and a woman-chief, offers honor and praise not only to the Goddess, and her daughters of the natural world, but to the many ordinary and extraordinary human women who are Her living embodiments.[5] The common tasks that she names are works that sustain, heal and enrich the world, making life possible and enjoyable for millions of people locally and globally. Even today, this work is carried out by millions of women throughout the world.

---

[4] *Iyanifa* is a priestly title in the Yoruba religious system that is granted to women who are considered "mothers of wisdom" or full diviners. See : Badejo, D. (1996b). *Osun Seegesi: The elegant deity of wealth, power and femininity (*pp. 90-93).Trenton, NJ: Africa World Press.

[5] While I have no desire to *essentialize* that work that women do as mothers, and child rearers, or to limit our capacities to work that is pre-industrial in nature (thus denying our intellectual, scientific, and scholarly abilities), the work that Teish names is still done by a majority of working class women all over the world.

I know that for some, the term, ‘Divine Feminist’[6] is quite confusing. I want to acknowledge Dr. Alka Arora, faculty member of the CIIS Women’s Spirituality Program for first coining this term. In what is commonly called the Western worldview – and I acknowledge that there are currently a variety of ‘Western’ worldviews – the sacred and secular realms, if not opposed, are at least separate. The term, ‘divine feminist’ represents my attempts to bridge these two very distinct and conflicting world views.

However, if we explore the work of borderlands/*nepantlera* theorist, Gloria Anzaldua (2007/1987, pp. 99-120) we find a discussion of the contested areas of conflict and convergence, which frame the diverse and opposing paradigms in which many of us live. In an essay titled “La Conciencia de la Mestiza/Towards a New Consciousness” (Anzaldua, 2007/1987, pp. 100) , Anzaldua refers to the theories of Mexican philosopher Jose Vasconcelos regarding *La Raza*, the multi-ethnic, bicultural people who emerged from the forced encounters between the Spanish conquistadores, and the Indigenous inhabitants of Latin America:

> Opposite to the theory of the pure Aryan, and to the politics of racial purity that white America practices, his theory is one of inclusivity. At the confluence of two or more genetic streams …this mixture of races rather than resulting in an inferior being, provides hybrid progeny, a mutable … species with a rich gene pool. From this racial, ideological, cultural and biological cross-pollinization, an ‘alien’ consciousness is presently in the making – a new *mestiza* consciousness, *una conciencia de mujer.* It is a consciousness of the Borderlands. (Anzaldua, 2007/1987, P. 99)

Developing this theory further, Anzaldua continues:

> Cradled in one culture, sandwiched between two cultures, straddling all three cultures and their value systems, *la mestiza* undergoes a struggle of flesh, a struggle of borders, an inner war. Like all people, we perceive the version of reality that our culture communicates. Like others having or living in more than one culture, we get multiple, often opposing messages. The coming together of two self-consistent but habitually incompatible frames of reference causes *un choque,* a cultural collision. (Anzaldua, 2007/1987, P. 100)

While all of us do not (and should not) claim a *mestiza* identity, I would argue that many of us straddle traditional, non-traditional, and modern world views. We are trying to walk a path of integrity that honors and integrates older more holistic practices, while remaining within the framework of the modern techo-industrial West in which we have been raised.

A *divine feminist* is one who walks the contested borderlands between secular feminisms, religious studies, and ethnic/indigenous studies. We stand at the crossroads where goddess studies, feminist studies in religion, and newer spiritual frameworks elaborated by people of color and others involved in the reclamation and renewal of women and other oppressed gender’s ancient and contemporary roles, rights and powers meet. We weave together Euro-centric perspectives on philosophy and religion with older frameworks drawn from goddess studies, ethnic/indigenous studies and new paradigms in women, gender and disability studies, to name a few of the transdisciplinary areas that women's spirituality touches upon. We are claiming and reclaiming ancestral traditions. We are using our knowledge, and the knowledge and spirituality of our ancestors to inform our activism. We are uncovering the original women-honoring traditions buried in frameworks labeled patriarchal; we are making alliances across difference and continually interrogating and challenging our work and the work of others.

---

[6] This paper by Dr. Alka Arora, titled: *The Divine Feminist*, was part of a panel at 2016 Founders Symposium at CIIS and is included in this special issue of Integral Review (Vol. 13, No. 1, 2017).

While the terrain that the divine feminist walks is contradictory and perplexing, its breadth allows us to be more fully inclusive of our human lives and our human struggles. The term, 'divine feminist', is related to, but not synonymous with, the term 'Divine Feminine'. The Divine Feminine is often used to describe female divinities. However, when we imagine female divinity, we all too often imagine a 'Divine Feminine', which is perfect: healthy, able-bodied, symmetrical and *perfectly* beautiful. All too often, we fall into a trap in which we choose the unattainable 'ideal', rather than the material, the real, and the mundane in order to represent what is spiritual and 'beautiful'.

I've been studying women's visionary art for a long time – and I finally understand what some of my students who reject the term 'Divine Feminine' have been telling me. If we talk about a 'Divine Feminine'; surely she's different from the fat, imperfect, female body that sweats besides us at the gym, or who squats, ragged, smelly and homeless on the street. The slender, full-breasted, long-haired, narrow-waisted, full-hipped 'Divine Feminine' that is celebrated in contemporary artistic depictions of female divinity all too often looks like a white, brown, or golden-skinned Barbie doll, or even worse, a Playboy pinup[7].

Even in women's goddess circles, we rarely see or imagine the Divine Feminine as embodied by the gender queer youth or the middle aged butch; she's not the disabled woman with cerebral palsy or an elderly woman of color living with dementia in a nursing home. In the dominant culture worldview, which confines us to binary boxes – i.e. good versus evil, beautiful versus ugly, white versus non-white, young versus old, able-bodied versus disabled, cis-gender male versus cis-gender female – we only count if we are able to successfully present as embodying the qualities deemed most worthy by the dominant culture.

In addition, dominant culture values may be as embedded in the alternative movements we create, as they are in the systems we struggle against. All too often, the Goddess – who in some traditions is a primary spiritual icon of liberation – is embodied by images reflecting the values of the dominant culture, rather than images that reflect our actual cis-or-trans-gendered bodies.

Fortunately, all of us have roots in indigenous traditions that valorized the 'real' or material world as well as the spiritual realm. In many 'traditional' indigenous world views, everything is part of Creation – and everything is sacred. In a poem written by Native American (Mvskoke Nation) Joy Harjo titled "Remember," the poet states:

---

[7] While some readers may view Barbie dolls and Playboy pinups as positive, I see them as representing unrealistic and/or unattainable templates of female embodiment, since the form they present is rarely seen naturally, and many women and girls experience mental, physical and emotional suffering in their attempts to attain this ideal.

Remember the sky that you were born under,
know each of the star's stories.
Remember the moon, know who she is. I met her
in a bar once in Iowa City.
Remember the sun's birth at dawn, that is the
strongest point of time. Remember sundown
and the giving away to night.
Remember your birth, how your mother struggled
to give you form and breath. You are evidence of
her life, and her mother's, and hers.
Remember your father. He is your life, also.
Remember the earth whose skin you are:
red earth, black earth, yellow earth, white earth,
brown earth, we are earth.
Remember the plants, trees, animal life who all have their
tribes, their families, their histories, too. Talk to them,
listen to them. They are alive poems.
Remember the wind. Remember her voice. She knows the
origin of the universe. I heard her singing Kiowa war
dance songs at the corner of Fourth and Central once.
Remember that you are all people and that all people
are you.
Remember that you are this universe and that this
universe is you.
Remember that all is motion, is growing, is you.
Remember that language comes from this.
Remember the dance that language is, that life is.
Remember. (Harjo, 1991, p. 234)

This poem reminds us that in the indigenous world, *everything* is sacred. Intellectually, I had been aware of this for decades, but its true meaning eluded me. The good, the bad, the human, and the non-human – are all part of the Indigenous circle of life. My friend, teacher, and colleague, Angelita Borbon, states that indigenous thought is based on the three R's: respect, relationship and reciprocity. We live, she says, in an embodied universe in which there are numerous living entities, many of whom are not human. Our life is conducted in *relationship* to these entities, which include – but are not limited to – the elements of earth, air, fire, water, metal and rock; the life forms which share the earth with us – represented by plants, animals, birds, insects, microbes, and fish – and the mountains, rivers, caves, trees or oceans which embody sacred sites.

According to San Francisco elder, healer, and Indigenous spiritual teacher, Dr. Concha Saucedo-Martinez, co-founder of Instituto De La Raza in San Francisco, we owe these powers *respect*, since they are the forces that make life possible. The Four Directions are not compass directions, metaphors or psychological archetypes – they are the spiritual powers and sacred entities that enable human beings to live on this planet.

In private conversations with me when we were doing diversity trainings together in the 1980s, Borbon explained the concept of reciprocity to me. Reciprocity, according to Borbon (personal communication, n.d.), means that what we do as humans, comes back to us. It’s no surprise to indigenous peoples that if we pollute the land and the waters, that this act will affect our lives – and the lives of our children and grandchildren. All things are connected and the acts we take or don’t take have real repercussions in the world.

In this world of sacred sentient life, we are all sacred because that’s how we were born. We’re not less sacred because we’re disabled or different; the drunken woman who has abandoned her child has lost her way, but she’s still a sacred being. She needs help and healing – and if she persists in following a particular road, certain consequences will occur. However she’s still a child of Creator and a manifestation of the Divine. And in some Indigenous traditions, which understand and accept the many roads that humans travel, there may be a special deity for the thief or the prostitute or the one who’s lost their way. *All* are part of the circle of life. The idealized Divine Feminine may not live in this realm, but the divine feminist transverses it. She knows that roads can change, and that light follows darkness and that darkness follows light. Braided together like life and death, suffering and ease, the divine feminist is the common woman that Judy Grahn writes about.

> She’s a copper headed waitress,
> tired and sharp-worded, she hides
> her bad brown tooth behind a wicked
> smile, and flicks her ass
> out of habit, to fend off the pass
> that passes for affection.
> She keeps her mind the way men
> keep a knife – keen to strip the game
> down to her size. She has a thin spine,
> swallows her eggs cold, and tells lies.
> She slaps a wet rag at the truck drivers
> if they should complain. She understands
> the necessity for pain, turns away
> the smaller tips, out of pride, and
> keeps a flask under the counter. Once,
> she shot a lover who misused her child.
> Before she got out of jail, the courts had pounced
> and given the child away. Like some isolated lake,
> her flat blue eyes take care of their own stark
> bottoms. Her hands are nervous, curled, ready
> to scrape.
> The common woman is as common
> as a rattlesnake. (Grahn, 2009, pp. 10-11)

She’s the resister, the survivor, the teacher, the healer. She’s the abused woman leading other women out of brothels; the acid burned woman who walks with her scars publically and tells others to resist. She's Lora Jo Foo[8], the daughter of a Chinatown sweatshop worker – and a garment worker, herself at 11 – who grew up to become a labor organizer and attorney – and who broke the silence about her family's life in a memoir of photographs that document her healing. She's Dorothy Allison (1994), the lesbian organizer of battered women's shelters who was kicked out of the feminist movement because of her alternative sexual practices. She's Amina Wadud, African-American Qur'anic theologian who proudly asserts:

> As a descent of African slave women, I have carried the awareness that my ancestors were not given any choice to determine how much of their bodies would be exposed at the auction block or in their living conditions. So, I chose intentionally to cover my body as a means of reflecting my historical identity, personal dignity and sexual integrity. (Wadud, 2006, p. 221)

She's Doris Davis, an orthodox Jewish teacher from Long Island whose husband refused to grant her a divorce – effectively preventing her from being able to re-marry within her community. With help from the Organization for the Resolution of Agunot[9], she led rallies outside of her husband's home and posted his photo in synagogues in Brooklyn – protests which eventually led to his granting her a divorce (Brooten, 2010).

She's you and me and women we'll never see – and yes she's divine because what's more spiritual than our liberty and freedom? What's more spiritual than struggling to stay alive and make a better world for those you love – your family, your children, your community?

The issue of spirituality can also be problematic. The linkage of social oppression with dominant culture religious traditions has a long and multicultural history. That legacy is very much alive today. Many feminist scholars are acutely aware of how women, LGBTQIQASGLP[10] people, and queer/third gender communities are oppressed by fundamentalist religious traditions both here and abroad. Christianity taught to enslaved Africans by their Euro-American owners justified slavery and encouraged the slaves to be content with their lot. The ill treatment of Dalit people in India was justified by certain strands of Hindu religion. And at different points in time, all three Abrahamic religions accepted the fact that female captives could become the sexual slaves of men who owned them. This means, and let me be explicit, that these women could be raped at will.

That said, religion has also been used to support resistance. The verse *Osa Meji,* is one of the Yoruba *odu* found in *Odu Ifa,* the compendium of stories, proverbs, divinations and moral and ethical guidelines, which form the body of the sacred oral 'texts' of traditional Yoruba religion. There we find that even when sexism is postulated to exist at the time of Creation, it turns out not to be sanctioned by the Supreme Being. According to *Osa Meji,* when the original (17 in some versions and 401 in others) orishas, or deities, came to the earth to make the world habitable, they excluded Oshun, the only female deity who travelled with them, from their deliberations. In his modern translation of the Yoruba text, Maulana Karenga writes:

---

[9] The Organization for the Resolution of Agunot is a non-profit organization based in New York whose mission is to "eliminate the infliction of abuse within the Jewish divorce process." http://www.getora.org/#!about-us/cxeg accessed 6/28/2016.

[10] LGBTQUIQASGLP or lesbian, gay, bisexual, transgender, queer, intersex, questioning, asexual, same gender loving pansexual.

> This is the teaching of Ifa for Odu
> 　　Obarisa and Ogun,
> When they were coming from heaven to earth.
> Odu asked: “O Olodumare, *Lord of Heaven,*
> 　　this earth where we are going,
> What will happen when we arrive there”
> Olodumare said that they were going to make
> 　　the world
> So that the world will be good.
> He also said that everything that they were
> 　　going to do there,
> He would give them the ase, power and authority,
> 　　to accomplish it,
> So that it would be done well.
> Odu said “O Olodumare this earth where
> 　　we are going,
> Ogun has the power to wage war.
> And Obarisa has the ase to do anything
> 　　He wishes to do.
> What is my power?”
> Olodumare said: “you will be their mother forever.
> And you will also sustain the world.”
> Olodumare, then gave her the power
> And when he gave her power, he gave her
> 　　the *spirit* power of the bird.
> It was then that he gave women the power
> 　　and authority so that anything men
> 　　wished to do,
> They could not dare to do it successfully
> 　　without women.
> Odu said that everything that people would
> 　　want to do,
> If they do not include women,
> It will not be possible.
> Obrisa said that people should always respect
> 　　women greatly.
> For if they always respect women greatly, the world
> 　　will be in right order
> Pay homage; give respect to women.
> Indeed, it is woman who brought us into being
> Before we became recognized as human beings.
> The wisdom of the world belongs to women.
> Give respect to women then.

Indeed it was a woman who brought
us into being.
Before we became recognized as human beings. (Karenga, 1999, pp. 72-74)

Women and other oppressed genders are certainly at the heart of feminism as an activist enterprise. This verse, which is as old as the Yoruba creation story, helps us understand how long sexism has existed even in (some) non-western cultures. However the fact that sexism has existed for millennia, does not mean that it has always existed[11] – nor does it mean that women have always accepted it.

If we review the term, 'womanist', which was coined by Alice Walker[12], I believe we can better understand the term, 'divine feminist'. While Walker had used the term *womanism* before, it is in the book, *In Search of Our Mothers' Gardens: Womanist Prose* (Walker, 1983), that she first fully defined the term, *womanist*.[13] Walker developed this term to differentiate between the feminist (or liberatory) activism of Black women and the feminist activism of Euro-American women.

(1976). *When god was a woman.* New York: Harvest/HBJ, have all challenged the notion of the continuous existence of sexism/patriarchy, arguing that Neolithic/Paleolithic artifacts suggest a veneration of the feminine, resulting in egalitarian/partnership/gynocratic societies. Other indigenous scholars: Allen, P. G. (1992) *The sacred hoop: Recovering the feminine in American Indian traditions* (2nd Ed). Boston: Beacon Press; Talamantez, I. (1991). Images of the feminine in Apache religious tradition. In Cooey, P. M., William R. E., and McDaniel, J.B. (Eds.), *After patriarchy: Feminist transformations of the world religions* (pp.131-144). Maryknoll, NY: Orbis Books, have suggested that some American Indian societies never adopted patriarchal structures and are matrilineal, matriarchal, or gynocratic.

[12] According to Layli Phillips (now Maparyan), the term, *womanism*, was independently coined by three separate writers during the 80's: Alice Walker, Chikwenye Ogunyemi, and Clenora Hudson-Weems (who was very specific about using the term *Africana womanism).* See: Phillips, L. (2006). Introduction: Womanist on its own. In *The womanist reader* (pp. xix-xx), Layli Phillips (Ed.). New York: Routledge, Taylor and Francis Group.

[13] "Womanist: 1. From *womanish.* (Opp. of "girlish," i.e. frivolous, irresponsible, not serious.) A black feminist or feminist of color. From the black folk expression of mothers to female children, "You acting womanish," i.e. like a woman. Usually referring to outrageous, audacious, courageous or *willful* behavior. Wanting to know more and in greater depth than is considered "good" for one. Interested in grown-up doings. Acting grown up. Being grown up. Interchangeable with another black folk expression: "You trying to be grown." Responsible. In charge. *Serious.* 2. Also: A woman who loves other women, sexually and/or nonsexually. Appreciates and prefers women's culture, women's emotional flexibility (values tears as natural counterbalance of laughter), and women's strength. Sometimes loves individual men, sexually and/or nonsexually. Committed to survival and wholeness of entire people, male *and* female. Not a separatist, except periodically, for health. Traditionally universalist, as in: "Mama, why are we brown, pink, and yellow, and our cousins are white beige, and black?" Ans.: "Well, you know the colored race is just like a flower garden, with every color flower represented." Traditionally capable, as in: "Mama, I'm walking to Canada and I'm taking you and a bunch of other slaves with me." Reply: "It wouldn't be the first time." 3. Loves music. Loves dance. Loves the moon. Loves the Spirit. Loves love and food and

According to Karla Simcikova (2007), “This definition . . . was in many ways a response to the white feminist movement of the time and its agenda, which was not particularly inclusive of, or sensitive to black women’s issues” (p. 11).

Beginning with the statement that a *womanist* was a Black feminist or feminist of color (p. 11), Walker’s four part definition focused attention on Black women’s historic and contemporary ability to take leadership in liberation struggles benefiting *all* members of the African American community. However, a womanist, for Walker, was not only a social activist. Walker’s concept of womanism validated Black women’s ability to love, support and nurture women and men “sexually and non-sexually” (p. 11). She honored the diversity, beauty and ‘*roundness*’ (p. 12) of Black women’s physical forms, and proclaimed the importance of rest, healing, and self-care. She listed music, dance, Spirit, and the Folk among the elements loved by womanists.

Walker’s holistic definition of womanism is also inclusive of people of many colors and ethnicities. She defines a womanist as a “universalist,” (p. 10) rather than a separatist, and she uses the metaphors of a garden of flowers and a family of many colors.

While some Black women of diverse identities have embraced the term, ‘womanism’, others have rejected it. Some Black women prefer to be called Black feminists. Some indigenous women prefer the term *tribalists* (Mehesuah, 2003, pp. 159-171) and there are others who support or reject Walker’s definition of “womanist” either in whole or in part.[14]

While these controversies continue, the work of supporting, improving, or reclaiming culturally appropriate rights of women and other genders is alive and well in a multitude of Indigenous and African societies. Writing of Africa, Filomina Steady (1981) states:

> The birthplace of human life must also be the birthplace of human struggles, and feminist consciousness must in some way be related to the earliest divisions of labor according to sex on the continent. But even more significant is the fact that the forms of social organization which approach sexual equality, in addition to matrilineal societies where women are central, can be found on the African continent . . . Above all, true feminism is impossible without intensive involvement in production. All over the African diaspora, but in particular on the continent, the black woman’s role in this regard is paramount. It can therefore be stated with much justification that the black woman is to a large extent the original feminist. (pp. 35-36)

If we review women’s roles in selected areas of West Africa, we see that even in the patriarchal societies of the Yoruba and the Ibo women: 1) held social and political roles of authority, 2) worked outside the home, 3) had the right to engage in money-making commercial activities and, 4) held roles of spiritual authority in their culture’s religious institutions. The term ‘mother’ which in the

---

roundness. Loves struggle. Loves the Folk. Loves herself. *Regardless.* 4. Womanist is to feminist as purple to lavender. Walker, A. (1983). *In search of our mothers’ gardens: Womanist prose* (pp. xi-xii). San Diego: Harcourt, Brace, Jovanovich.

See, also: Hudson-Weems, C. (2006). Africana womanism. In *The Womanist Reader* (pp. 44-54), Layli Phillips (Ed.). New York: Routledge, Taylor and Francis Group.

west connotes a lack of power in the ‘outside world’ of politics, economics, and religion, is a term of authority and agency within many African societies. The Yoruba even have a term, *iyalode*, “mother of the outside” (Badejo, 1996a, p.8), which is used as a title for the women who hold authoritative roles in the political, economic and spiritual realms – e.g. the woman chief of the market place, the chief of the women’s military organization, or the senior priestess who is involved with politics of the land. According to Oyewumi, kingship was not denied to Yoruba women, and she argues that several of the “kings” in Yoruba history were actually female. [15] Childbirth was neither unimportant nor secular; in a culture where the goal of existence was to be reborn again and again, it reflected spiritual harmony, social balance and **empowerment** (Badejo,1996a, pp. 67-101).

Rejected by many modern day feminists as essentialist, the powers of birth giving and/or life making were – and in some cases still are – seen as magical, mysterious and **empowering** in many African socio-spiritual contexts (Badejo, 1996a). The figure of a woman kneeling in the traditional (active) stance of giving birth was often depicted in pre-colonial and/or “traditional” Yoruba sculptures. Stripping naked and exposing their vulvas was an act of women’s power in many areas of pre-colonial Africa – especially when done by married or elderly women – and this has been repeatedly employed by African women of the 20th century in protests against government taxation, ecological depredations by oil companies and in support of peacemaking efforts[16].

Even in patriarchal settings, Nigeria’s Ibo women could (collectively) go on sex strikes and “sit on a man” – e.g. go to war against an individual or a group who aroused their anger. Judith Van Allen, writes:

> "Sitting on a man" or a woman, boycotts and strikes were the women's main weapons. To "sit on" or "make war on" a man involved gathering at his compound, sometimes late at night, dancing, singing scurrilous songs which detailed the women's grievances against him and often called his manhood into question, banging on his hut with the pestles women used for pounding yams, and perhaps demolishing his hut or plastering it with mud and roughing him up a bit. A man might be sanctioned in this way for mistreating his wife, for violating the women's market rules, or for letting his cows eat the women's crops. . . . In tackling men as a group, women used boycotts and strikes. Harris describes a case in which, after repeated requests by the women for the paths to the market to be cleared (a male responsibility), all the women refused to cook for their husbands until the request was carried out. For this

> boycott to be effective, all women had to cooperate so that men could not go and eat with their brothers. (Van Allen, 1972, p. 170)

I’ve cited these examples to make clear that women in Africa were not waiting to learn about their oppression from Euro-American feminists. It is true that sexism existed in Africa prior to contact with Islam, Christianity and European colonialism, but many cultures in Africa, while not based on a model of gender *equity*, were based on the principle of *complementarity* in gender relationships. In such cultures, the powers of men were believed to be *balanced* by the power of women, ensuring that social, spiritual and ecologic harmony prevailed.

Women often had power not as individuals but as part of a collectivity of women. Among the Nnobi of Nigeria, for example, there was a Women’s Council that was responsible for the welfare of all Nnobi women: it set rules to regulate or protect women against physical abuse (Amadiume, 1998, p. 66), regulated the market, and independently acted to support the welfare of the town (Amadiume, 1998). The *Agba Ekwe*, or most highly titled woman, was considered to be a representative of the Goddess Idemili herself, and only she and the shrine priest could consult with the Goddess directly. Under Christianity and colonization, however, the authority and titles of men were readily translated into male norms of the colonial administration, while the authority and responsibilities of powerful women were seen as “pagan” and discontinued.

Most of us understand that the struggle of women for justice and empowerment is a global one. My description of the precolonial power of African women is meant to help us understand that the issue of women’s rights and powers in selected patriarchal non-Western societies is more complex than many of us have considered. However while most of us would support political systems that provide justice and equality for women, many of us don’t make the connection between liberation struggles and the practice of spirituality. For many of us, religion has created a divide between social justice and spirituality, for we have been raised either in an entirely secular world, or one in which the material and spiritual realms are seen as separate.

We all know the world needs to change. How we do it, with whom we do it, and with what tools, are some of the important questions we need to ask. While we often contrast contemplative spiritual traditions with socially engaged or activist ones, I believe that a closer examination of diverse, traditional, contemporary and/or indigenous spiritual traditions from around the world reveal that the questions we face today were not unknown to peoples of the past, nor to their colonized and oppressed descendants.

In some contemplative religious traditions, the material world, while beautiful, is not divine. Divinity and sacredness – belong to a realm outside of our material reality. If in some traditions we suffer in the physical world, it is because of our transgressions in a previous life. In others, our suffering is merely the reality of our life on earth. Only after our death and release to a heavenly realm, or our rebirth as a member of a different caste or gender, will our earthly suffering come to an end and be redeemed.

In still other traditions, some of which are branches of the same contemplative religions that see suffering as a normal part of life, we are called to take action to relive the suffering of all sentient beings. The Bodhisattva Vow of Mahayana Buddhist tradition has been interpreted as meaning that we vow to return again and again to the world until all sentient beings have attained enlightenment. The engaged Buddhism of Vietnamese Buddhist monks led some to burn themselves to death to protest the Vietnam war, and it encouraged others to provide healing to wounded soldiers and civilians on both sides of the war. In many Jewish traditions one, is expected to engage in *tikkun olam*, the repair of the world, which has been interpreted by some as meaning that one is obligated to take righteous *social action* to foster the creation of a peaceful and egalitarian world that honors all races, ethnicities, spiritualities, orientations, genders, and abilities.

Many of the Indigenous peoples of the Americas understand that their spirituality is intrinsically linked to liberation from oppression. The ability to practice many Indigenous religions is often linked to particular landscapes which shelter the sacred sites, plants and other items that are necessary for the proper spiritual practices of particular First Nations peoples (McLeod, 2001).The right of access to their traditional lands, along with the right to speak the languages in which their spiritual traditions are embedded, and the right to have custody of their children and to train them in their ancestral ways, were rights that were denied to many Indigenous inhabitants of the USA for centuries. The reclaiming of these rights – and they have not yet been granted to all First Nations peoples of the USA – has only come about because of political, spiritual and activist struggles.

Whether we accept the notion of a spiritual or ensouled universe or find ourselves moved by legacies of human activism for liberation, our profound human connection to the natural world remains. I'd like to close with a poem by Alice Walker that invokes the union of spirituality and social justice – and that reminds us of the natural world's ability not only to sustain our bodies but to feed our souls. It's called "Torture":

> When they torture your mother /Plant a tree
> When they torture your father / Plant a tree
> When they torture your brother/ and your sister
> When they assassinate your leaders/ and lovers/ Plant a tree
> When they torture you/ too bad / to talk/ Plant a tree
> When they begin to torture / The trees / And cut down the forest
> they have made
> Start another. (Walker, 1989, p. 63)

May we remember and follow this ancient and indigenous wisdom in the days to come.

The Borderlands Feminine:
A Feminist, Decolonial Framework for Re-membering Motherlines in South Asia/Transnational Culture

Monica Mody[1]

Abstract: This paper uses Gloria Anzaldúa's borderlands framework to resignify and recover the marginalized, forgotten sacred feminine and, thereby, South Asian motherlines. The borderlands is conceived of as a new consciousness, an alternative to that which is written in history. It offers a radical synthesis of spiritual healing with anti-oppression work. Creating self-affirming, complex images of female identity, and making revisionist myths—while engaging the self in relation to culture— constitutes a decolonial practice. It enables South Asian women—as the Others of colonial modernity and brahmanical patriarchy—to renew their relation to an episteme of the sacred that liberates their voices, vitality, and authority. The post-secular sacred locates as essential a critical interrogation of all forms of oppression. The researcher enacts her decolonial recovery at the edges of her South Asian/brown postcolonial feminist subjectivity. The borderlands framework makes possible a profoundly relational, integrative onto-epistemological praxis that forefronts the grandmothers, the foremothers, and the experiences of women of color on their own terms.

Key Words: Borderlands Framework, Decolonization, Female Identity, Gloria Anzaldúa, Sacred Feminine, South Asian Motherlines.

Introduction

Chicana cultural theorist and feminist Gloria Anzaldúa's (1987) borderlands framework offers a radical synthesis of spiritual healing with anti-oppression work. By refusing to prioritize one over the other, she creates a multimodal, living, organic theory that offers an interstitial home for postmodern, postnational, postcolonial identities. Borderlands consciousness makes possible reconciliation and integration by moving "toward a more whole perspective, one that includes rather than excludes" (Anzaldúa, 1987, p. 79). This is a profoundly relational and integrative onto-

epistemological praxis. In this paper, I examine how the borderlands framework constructs bridges between the past and the present, the old and the new, myth and imagination and reality, post-colonial and pre-colonial. These structures and flows are not readily visible in Western modernity. Creating self-affirming, complex images of the feminine and of South Asian motherlines makes it possible for South Asian women—the Others of colonial modernity and brahmanical patriarchy—to renew their relation to an episteme of the sacred that liberates their voices, vitality, and authority. It further enables transcultural, transnational interventions that acknowledge my South Asian/brown postcolonial feminist subjectivity.

For Anzaldúa (1987), the *borderlands* refer to a consciousness at the confluence of two or more cultural, racial, ideological, or spiritual values that makes "crossing over" (p. 77) possible. The metaphor of borderlands does not narrowly connote mere geopolitical borders (Anzaldúa's theory was specifically informed by the U.S./Mexico border), but invokes the psychic, emotional, and sexual dimensions of the terrain of intermingling (Anzaldúa & Keating, 2000, p. 176). Feminist and comparative politics scholar Leela Fernandes (2013) writes that it is the borders of her psyche that provide, for Anzaldúa, the psychic/political/cultural space to move beyond the violence of the territorialized borders she was confronted with (p. 106).

Anzaldúa (1987) considers the task of breaking down of dualisms one of innovation, after chemist Ilya Prigogine's work on "dissipative structures" as a new source of order (p. 120). Further, this is a task of healing:

> At some point, on our way to a new consciousness, we will have to leave the opposite bank, the split between the two mortal combatants somehow healed so that we are on both shores at once and, at once, see through serpent and eagle eyes. (Anzaldúa, 1987, pp.78–79)

This overlapping consciousness makes possible reconciliation and integration. Decolonial theorist Nelson Maldonado-Torres (2012) writes that this self "is not a continent or a separate island, but, rather, a border, a point of encounter, an intersection, or even an archipelago, understood as a point of relation with other selves" (p. 198). In her movement "toward a more whole perspective, one that includes rather than excludes" (Anzaldúa, 1987, p. 79), the border dweller changes and heals the split at the root of consciousness. This is the opus, the great alchemical work—what Anzaldúa (1987) also terms spiritual mestizaje (p. 103).

Anzaldúa's (1987) other names for the both/and consciousness of the borderlands—*new mestiza* or *mestiza consciousness*—reflect her Chicana positionality. She writes:

> The work of *mestiza* consciousness is to break down the subject-object duality that keeps her a prisoner and to show in the flesh and through the images in her work how duality is transcended. The answer to the problems between the white race and the colored, between males and females, lies in healing the split that originates in the very foundation of our lives, our culture, our language, our thoughts. (p. 80)

Like other Chicana/o scholars and activists, Anzaldúa was engaged in a reimagining and reformulating of the ancestral traditions of the indigenous Aztec and Toltec people. Laura Perez (1998) reminds us that this was a politics of memory. In drawing from indigenous cultures that are politically oppositional to (neo)colonizing cultural and religious systems, and then recoding them, cultural agents enact a spirituality that can help redefine worldviews and identities at the borderlands. In an attempt to establish a common worldview that is “at odds with the reigning capitalist culture of extreme exploitation of the planet and human beings” (Perez, 1998, 'Membering the Spirit section, para. 3), the mestiza borrows from and synthesizes diverse beliefs and practices. This is a decolonial gesture when practiced by the “marginalized, the mutable, and the unarticulated” (Perez, 1998, Beyond the Susto of Nepantla section, para. 6), and allows the borderlands to become for them a full and central, ever-shifting, place of knowing and being. Its seeking of resonance prevents the borderlands from being invoked as “yet another . . . peripheral resource in the center’s production of meaning” (Perez, 1998, Beyond the Susto of Nepantla section, para. 6). The bridge that is constructed through memory between the past and the present, the old and the new, enables transcultural affirmations of the feminine, the queer, the colored, the colonized, the indigenous. It reclaims and reconstructs for them the fullness of their humanity.

Throughout her writings, Anzaldúa repeatedly underscores the need for new forms of alliances between women, genders, cultures, races and other social positions, material and nonmaterial worlds, humans and nonhumans. Instead of monolithic, oppositional identities, her framework foregrounds alliance-making and forging commonalities from a holistic, relational perspective.

Anzaldúa’s activism embodies what womanist/feminist scholar AnaLouise Keating calls her metaphysics of interconnectedness (Anzaldúa & Keating, 2000, p. 11). Her risk-taking not only opens the door for other scholars to invent new forms of alliances and identities where they may bring in spiritual realities, imaginal realities, and their inner subjective life, but also empowers them to discuss these on an equal footing with issues such as race, class, age, and ethnicity (Anzaldúa & Keating, 2000, p. 144). In the serpent movement of spiritual mestizaje, justice and healing are envisioned hand in hand.

I turn to Anzaldúan thought as a framework for its inerrant capturing of my own lived experiences of borders, taking into account the effects of psychic, political, ideological, and gender borders on my own embodied belonging and efficaciousness in the world. As Cathryn Merla-Watson (2013) writes, “The domain of theory…should be a collective enterprise of suturing multiple constituent elements of identity and lived experience” (p. 226). India—just as the other colonies of Europe—was subjected to the more repressive aspects of Enlightenment rationality, expressing the colonial state’s anxieties about order and control (Siddiqi, 2002). This paper seeks to connect the parts of my identity that were gradually split off under the governing ideologies of rational secular colonialist modernism: ancestral, nonwestern, fierce, female, sexual. It is an attempt to reconstruct a consciousness of the prepatriarchal feminine while living under patriarchy’s gaze. It is an attempt to reconcile the oppressor in me with the oppressed in me. It is an attempt to be in integrity both as a scholar and as an artist—for I realize that unless I do this work, I cannot show up in my fullness in either scholarship or art; nor can I do the work of countering the logic of domination.

Historian and Ethnic Studies scholar Emma Pérez (1999) envisions the decolonial imaginary as “a rupturing space, the alternative to that which is written in history” (p. 6), and the apparatus that allows the move between the colonial and the postcolonial. The Anzaldúan notion of borderlands demands a similar willingness to be re-membered. The dismembered parts come together to synthesize a new being. We do not stop at critiquing standards of Western rationality and objectivity; we create new patterns of rationality and objectivity informed by the heretofore suppressed feminine and "primitive." Accessing these parts in ourselves, we gradually decolonize our being. We de-link from Western modernity and open up to what Partha Chatterjee terms "our modernity" (as cited in Mignolo, 2012, p. 27), locating possibilities of other temporalities.

The excavation of meanings and practices that are non-Eurocentric and non-androcentric is a slow, layered process that unfolds in a spirallic fashion. The circle or spiral is the pattern or "means-by-which" the eternal cycle of birth-death-and-rebirth—in which all forms of creation are eternally turning and evolving—can be experienced (Wilshire, 1989, p. 102). Writing that follows a cyclical pattern rather than a linear form is able to return to ideas or themes "at intervals with different levels of understanding" (Wilson, 2008, p. 42). Anzaldúa (2002) sees developing a new consciousness as a cyclical, ceaseless process (p. 562). In the spiral, time is not a linear construct. What happens here can affect the past, present, and future—it can enliven the body, and heal ancestral and future generations. The spiral connects the center and the periphery, the inner and the outer. This intimate connection means that as the spiral moves outward, individual and collective actions of spiritual mestizaje contain the possibility of renewing the sacred.

Borders and Vitality: A Personal Account

Stories, memories, voices, and energies of other kind can get trapped in the liminal state between borders, if the borders are not permeable enough to allow movements or crossovers. This became vividly clear to me when—during a vision in early 2016—I found my female ancestors immured in a tunnel-like underworld.

Their life spark and vitality had been suppressed or stolen away, they said, by the heavy mantle of patriarchy. The term *patriarchy* rightly elicits much debate and critique in feminist and other scholarship. For example, scholars caution that systems of male dominance be analyzed with attention to power differentials in their cultural, temporal, spatial, and other intersectional dimensions, rather than be conceived of as universally monolithic, homogenous, ahistorical hierarchies (Kandiyoti, 1988; Patil, 2013). I have come to understand patriarchy not only as the institution that patrols the borders of gender roles and the sexuality of individuals of all genders. It is also a metonym for the experience of smallness, fear, rejection, shame, and lack of inner authority that accompanies many women on an ongoing basis—that for them is the only way in which they have experienced being women. It is the feeling of being cut off from something vital in themselves; of powerlessness at not having been able to change the tide. Based on evidence of pre-patriarchal, non-patriarchal, and matriarchal alternatives in early as well as living history, it has been theorized that patriarchal power structures are a cross-cultural historic development, linked with diminishment of the role and status of women (Gimbutas, 1991; Göttner-Abendroth, 2012; Sanday, 2002).

In the vision, I was in that dark space with my female ancestors, and they were asking me to write so they would—riding on the stream of the vital force living in words—come out.

Vitality, then, was for my ancestresses the key to liberating themselves from a history of institutional, structural oppression—and from history itself, which is often the oppressor's account made authoritative because of an imbalance in power. Linda Tuhiwai Smith (1999) notes the critique of history as a project of Western Enlightenment that has developed alongside imperial beliefs about the Other, assembled around totalizing, universalizing, evolutionist, and progressivist ideas (pp. 29–32). Feminist thinkers have further called out much of history as male-stream and noted that such accounts erase or sideline women's roles, and relegate their often complex enactions of agency to a simplistically conceptualized victimhood. Feminist theorist and political philosopher Mary Hawkesworth (2007) points to the "pervasiveness of the mistakes about the nature of women and their roles in history, politics, and society and the imperviousness of mistaken views to refutation" in androcentric scholarship (p. 95). Theologian Mary Daly (1978), creative spinster, suggests "hag-ography" and "hag-ology" as models women can adopt to uncover hidden histories of women—of Hags: "Hag-ographers perceive the hilarious hypocrisy of 'his' history." (p. 17).

The ancestresses' bidding of words as a means of introducing vitality made immediate sense to me as a writer. In poetry, I am deeply familiar with something moving in language that is beyond language—something that wells up from the pools of words and finds its way in us to animate or, as the case may be, to dishearten. The ancestresses were asking me to remember something further about the role *women* can play, in particular in their capacity as artists. My intuitive understandings found confirmation in the study of gynocentric American Indian cultures by Laguna Pueblo/Metis poet and scholar Paula Gunn Allen (1986). She writes:

> Pre-Conquest American Indian women valued their role as vitalizers. Through their bodies they could bring vital bodies into the world—a miraculous power whose potency does not diminish with industrial sophistication or time. They were mothers, and that word did not imply slaves, drudges, drones who are required to live only for others rather than for themselves as it does so tragically for many modern women. The ancient ones were empowered by their certain knowledge that the power to make life is the source of all power and that no other power can gainsay it. Nor is that power simply of biology, as modernists contentiously believe. When Thought Woman brought to life the twin sisters, she did not give birth to them in the biological sense. She sang over the medicine bundles that contained their potentials. With her singing and shaking she infused them with vitality. (p. 27)

Here, the power of generativity is not, as Gunn Allen makes clear, merely biological. Functioning in a ritual manner, using their bodies to bring vitality into the world, is what awards women the status of mothers. Creating embodied language is as much a sacred activity as giving human birth.

Motherlines

As soon as the ancestral behest was made, I realized it intended to secure healing and freedom for my ancestresses as much as the liberation of my own voice, life energy, and inner authority. I sensed for the first time the unbroken chain connecting me with my ancestresses, despite and through the trauma and the violence and the rupture. Poet and Jungian analyst Naomi Ruth Lowinsky (2009) gives the name *Motherline* to this sense of female continuity and interrelatedness.

The Motherline links generations of women to their future and their past—it honors the life stories, lore, and wisdom of their mothers and their grandmothers as the source of their own stories and wisdom. Lowinsky (2009) writes that the Motherline lies in the background of modern, patriarchal consciousness, and women (and men) are often unaware of their connection to it (p. 13). Which is why, she says, its very image "seems to evoke its absence, its loss, the pain we feel in the feminine" (p. 34). The feminine—like the masculine—is not a rigid gender category, but a vital concept: "the realm of mystery, the cyclical nature of life, the realm of women's bodies" (Lowinsky, 2009, p. 30).

An absence of the vital feminine was etched yet unmourned in my early experience of reality. Colonization and coloniality not only have shaped my personal history and the collective history of my people, they also created circumstances that disrupted and impaired motherlines. However, the process of erosion of motherlines in South Asia went on for centuries before the arrival of the European colonizers. Brahmanization in South Asia gradually changed the political, social, and cultural landscape, grafting itself onto autochthonous, folk traditions that worshipped the great mother (Göttner-Abendroth, 2012, p. 70). This prefiguration is not that of the self-sacrificial mother of a patriarchal consciousness:

> Mother-goddess can be interpreted as expressing ideas of power, autonomy, and primacy in the widest sense of the term. She conveys not so much the idea of physical motherhood but a worldview in which the creative power of femininity is central; the goddess mediates between life and death and contains in herself the possibility of regeneration. (Ganesh, 1990, p. 58).

Under the impact of Brahmanization, the mother goddess turned into a subservient spouse of the male deity relinquishing her autonomy. Baron Omar Rolf von Ehrenfels (as cited in Krishnaraj, 2010, p. 17) notes that strong mother-right elements persisted in India to a degree and extent more than elsewhere in the world. Yet gradually there was a sidelining of ways of living based on female-centered, earth-centered practices where knowledges were transmitted down the female lineages. These included lifeways founded on a knowledge of the woman as a medium for regulating the energies of the household, community, and the cosmos. Women had been custodians of ways of contacting the energy sources so as to initiate rites of auspiciousness (see Jayakar, 1990; Nagarajan, 2007), but the patriarchal hierarchy that permeated India via the Vedic caste system cut off many of these lineages and these knowledges.

Once superiority was established—of men over women, and of the upper castes especially Brahmins over the lower castes and the outside-caste/indigenous people—these Others of the Vedic caste patriarchy were relegated to the margins of history and of religious participation.

Ironically, even as India is known for its worship of the goddess and for its symbolic honoring of women, its women are penalized for going against tradition. They are simultaneously "made repositories of tradition but do not have access to their own tradition" (Krishnaraj, 2010, p. 17). There are exceptions that have kept nature-based, women-led rituals alive among folk and non-Vedic traditions such as Tantra (Jayakar, 1990; Khanna, 2000; Mookerjee & Khanna, 1996), but the overwhelmingly patriarchal, and increasingly nationalistic and xenophobic interpellation of religion in India has had a disastrous impact on the rights and sense of agency of its non-Brahmin, non-cisgender male Others.

Clearly, my ancestresses believe that the “female memories of power and energy” (Jayakar, 1990, p. xiii) can be reclaimed from the margins, at the borderlands. Female-bodied feminists who take on the challenge of engaging their discomfort with the primitive and the feminine—itself stemming from a modern rational, Western feminist interpretation of this notion—will find themselves recuperating the wholeness of their female, borderland selves. They may find themselves resuscitating their Motherline, and through this work learning—as I am—to be “open to others in relations of hospitality and generosity, and…commit ethically and politically to and for [an Other]” (Maldonado-Torres, 2012, p. 197). For, living at the borderlands and enacting a borderlands consciousness in contact with the ancestral, the premodern, the feminine, the embodied is as much about epistemic and ontological justice as it is about recovering the sacred in our post-secular narratives.

Women in the New Modernity of India

Goddesses in the religious life of the Indian subcontinent are attributed with power, autonomy, and primacy, while Indian women often remain subject to norms and violence regulating their social roles and conduct. Partha Chatterjee (1989) argues that a “new patriarchy” emerged in India with the origin of an anti-colonial nationalism (p. 627). The nationalist discourse, during its struggle against colonialism, invested the home and the world with polarized values (spiritual versus material). The home/world dichotomy came to be represented by gender roles, and women were assigned the responsibility for ensuring that the purity and superiority of India’s inner identity—its spiritual culture—remained intact. This purity was asserted as superior not only in opposition to westernization, but also in opposition to the “barbarism” and “irrationality” of the common, lower classes. The new modernity of India conferred upon women the dubious honor of becoming the bearers of a nationalistic morality, which, while claiming to revere woman as goddess or as mother, ironically narrows the primacy, scope, and sphere of her spiritual participation (Chatterjee, 1989, pp. 629–630).

Colonization made India an unbidden subject at the table of Western modernity and its offspring, Enlightenment rationality and secularism. Just as in the West, ontologies and epistemologies emerging from the province of tradition were seen as non-modern. This included “nature, the past, women, the feminine, the household, ‘the primitive,’ and loyalty to kin and tribe” (Harding, 2008, p. 8). The invention of religion itself was a by-product of colonialism, creating an arbitrary partition between the sacred and secular (Sen, 2013, p. 9). The brahmanical forms of practice were what came to be codified as Hinduism (King, 1999, p. 102).

According to Ashis Nandy (1995), there is a local meaning of secularism in India that does not place religion as outside politics, but connotes multireligious coexistence and equal respect for all religions. This notion of secularism draws its rationale from the broader traditions of religious practice in South Asia. This non-modern understanding has been losing ground to the Western model, especially with the continuing influence of nationalist ideologies in contemporary Indian polity. Nandy (1995) suggests that the religions, cultures and visions that have become silenced or marginalized in the dominant postcolonial narratives of secularism may hold the keys necessary to bringing in the transformations necessary to bring inter-communal harmony (p. 37). Lata Mani (2009) too advocates reexamining the meanings conferred by modernity upon the terms sacred and secular in order to carry out the work of social and personal transformation (p. 9).

Decolonizing the Feminine

The cooption of femininity by nationalistic morality in India has created the need for memory work where the feminine can be written in transcultural yet culturally specific, open-ended, fluid ways. The convergence of colonial rationality and brahmanical patriarchy has produced a condition where women struggle to remember their own sovereignty and authority. I seek to actively access and source non-brahmanical traditions for their possibilities of alternative, non-dominant spiritual knowledge and leadership for women. The call is for no mere romanticization of tradition, but for a participation in its reconstruction from the inside out so that it becomes a place of liberation for the Others of modernity, including women. This is a deeply self-willed, self-authorizing, feminist, decolonial act of reclaiming. It is a transformational practice that is about moving away from the epistemic hegemony of the West to knowledge making that privileges the non-West, the non-male, the non-white, and the non-European. Decolonization values the past as part of the present, not as something to reject. The past continues to “frame what becomes actuality from a horizon of possibilities” (Isasi-Díaz & Mendieta, 2012, p. 6). By decolonizing “spaces of belonging, sites of dispossession, claimed interstices, erased memories, and hushed stories” (Isasi-Díaz & Mendieta, 2012, p. 6), we create alternatives to that which is written in history.

Anzaldúa’s own work exemplifies this. As a Chicana and Mexicana, she invokes the indigenous sacred feminine to muddy the waters of the singular cultural identity, which is the subject of a Chicano Movement dominated by a masculinist and heterosexist cultural nationalism (Yarbro-Bejarano, 1994, p. 12). Reconstructed, the indigenous feminine figures are able to converge the past and the present, the cultural and the autobiographical psyche. Re-membered, they do not stay in the past—but claim the past, the present, and other temporal structures and flows that may not be recognizable in Western modernity. The border-crossing Coatlicue in Anzaldúa’s narrative, for example, reclaims her all-encompassing, multigendered aspects from the patriarchal, male-centered narratives that had split them off and cast them underground—claims Anzaldúa—and redefines the very contours of autonomy:

> And someone in me takes matters into our own hands… Mine. Ours. …And suddenly I feel everything rushing to a center, a nucleus. All the lost pieces of myself come flying from the deserts and the mountains and the valleys, magnetized towards that center. *Completa*. (Anzaldúa, 1987, p. 51)

Again, by reconnecting Guadalupe to indigenous goddesses, Anzaldúa recuperates the former’s capacity to include “the impure, mestizo/a, queer women and men for whom there is no room in dominant religious traditions” (Delgadillo, 2011, p. 26). Memory work becomes, for Anzaldúa, a relational exercise that connects individual and collective worlds at the borderlands: the displacements, pain, suffering, resistance, and empowerment therein. It enables her to formulate her complex, shifting subjectivity amidst a newly emerging collective identity. Her revisionist mythmaking is, further, a decolonial exercise: it enacts self-affirming images of female identity that create a rupture in the status-quo. These, Keating (2013) writes, are fluid, transcultural universals that “open up psychic spaces where alterations in consciousness can occur” (p. 118). Even as living on the borders is borne out of the necessity to survive, these multiple voicings of myth at the borderlands are necessary for women that do not identify with dominant Western heteropatriarchal tellings of the feminine to survive.

The current of nationalism in South Asia, like Chicano nationalism, is predicated upon an oppressive patriarchal and colonial gender structure. Nationalists have repeatedly attempted to wipe out India’s other, indigenous modernities since the latter do not produce the univocal, homogenous subject of the nation-state. This loss of plurality narrows the space available to women in the public and spiritual spheres. Cultural life, in private and public, continues to be framed within a discourse defined by masculine norms. Reflective of the power structures, goddesses become consorts of male gods, and women become subservient wives, mothers, and daughters of men who are the chief functionaries in the religious and sacred realms.

My situatedness within a transnational space gives me a sense of the ways in which national and transnational processes of oppression of the feminine overlap. Women’s experiences within the transnational empire are often imbricated, and the Anzaldúan model of reconstruction of the sacred feminine—and, via that, renewal of a post-secular sacred—gives me one strategy through which I may enact my interventions in the transnational/postcolonial imaginary of South Asia. By taking into account the Others of modernity so as to restructure our very understanding of the contours of modernity, the borderlands framework makes possible a meeting of the goals of social, political, epistemic, and ontological justice.

At the borderlands, it is not the dominant but the “other” ways of knowing that are valued (see Denzin et al., 2008). Other ways of knowing include those associated with women, nature, indigenous peoples, and people of color—and posit interests, feelings, passions, and the body as valid and authoritative sources of knowledge. They are able to connect the historically colonized Others to their own epistemology, ontology, and axiology—in other words, to their own autonomy, struggles, and resistance. I will end this paper with a proposal that poetry and autoethnography be considered as emergent integrative research strategies at the borderlands.

Both poetry and autoethnography disrupt inheritances of colonialism, imperialism, and androcentrism in the academy by making space for the epistemologies, ontologies, and interventions of feminist, non-European, indigenous scholars and scholars of color. Both enable nontraditional scholars to engage with knowledge production in the fullness of their sensory and social dimensions. They help nontraditional scholars make sense of their lives, by making possible integral discourses and helping them explore the “total complex of knowing”(McNiff, 2008, p. 34). Both offer “new ways to see” (Leavy, 2009, p. 254). The research methodologies of poetry and autoethnography embrace vulnerability, and demonstrate that emotional and psychological aspects are integral to social research. Likewise, they allow for a synthesis of the intellectual and aesthetic dimensions of research.

Through a process of analytic and creative reconstruction of the past and the present—the autobiographical and the cultural psyche—a transnational borderlands feminist can participate in the transformation not only of her own identity, but also of the collective identities of the communities she engages in. Here she stands in the limen, continually reaching for wholeness, a full participant in the unfolding of her own spiritual knowing. She puts herself back together again, in writing, in her anticolonial struggle—and she restores to her ancestresses their autonomy and vitality.

Chinmoyee and Mrinmoyee

Karabi Sen[1]

Abstract: Chinmoyee and Mrinmoyee are two different ways of looking at divinity in a feminine form. Chinmoyee emphasizes the attainment or realization or manifestation of higher consciousness as being divine while Mrinmoyee hugs the earth and brings home the deliberation that mrit or the earth is the mother of all being, including all forms of consciousness and deserves to be acclaimed as the deity. Mrit means earthen in Sanskrit and the earth is what all living creatures are made of. It is the spring, the sustenance of all life and also that to which life reverts back after a particular form of it ceases to function, to be regenerated as another form of life when the necessary conditions appear. Mrit, also called Mrittika in Sanskrit and "mati" in Bengali, is the mother of all life. It is etymologically connected to "matter," "matre," "madder" of the Indo-Iranian-European group of languages. Matter has been contemplated to be a lifeless substance by some philosophers but the term is essentially expressive of what we know to be the mother of us all---that from which we sprung, that in the womb of which we all came to be, slept and grew until we evolved further and that to which we return in final embrace until we transform into another being. Matter and mrit are viewed as lifeless by philosophers who try to preach ultimate divisions and the purpose of this paper is to overthrow such absolute dichotomies as false. The paper purports to establish that consciousness and matter are one and inseparable and hence Chinmoyee and Mrinmoyee are an identical entity.

Keywords: Chinmoyee, Feminine Divine, Indian Mythology, Mrinmoyee.

Chinmoyee and *Mrinmoyee* are both terms that refer to the divine understood as a female principle in the context of Hindu philosophy and religion. Chinmoyee represents the divinity in the feminine as being pure consciousness or *chit* while Mrinmoyee upholds *mrit*(dirt) or the mortal frame of flesh and blood of an everyday woman as the seat of goddesshood. Chinmoy was how the Vedanta represented Brahman and the devotional sects of the Hindu religion, particularly the Shaktas and the Vaishnavas, used the linguistically feminine version of the term or Chinmoyee to contemplate the feminine aspects of divinity. The concepts of chit and mrit have often been interpreted by philosophers and common people alike as opposites, much in the same sense that mind and matter are thought to be very different. Chinmoyee, being rooted in consciousness, has sometimes been seen as more thoroughly spiritual in comparison to Mrinmoyee, the mortal one, sprung from her origin in matter, in earth. It is my contention that such a division and the associated qualitative ranking between the two versions of the deity are untenable and consequently, unworthy of being pursued.

To many philosophers and devotees Chinmoyee and Mrinmoyee are one and the same deity, each term simply emphasizing two different aspects of the same divine principle. However, the belief systems underlying the two terms are entrenched in philosophies that have historically been quite apart. Time after time, the unresolved differences have found expression in controversies over the nature of Reality. Issues like change and permanence, appearances and reality, form and matter, monism and pluralism, the finite and the infinite, mind and matter, immanence and transcendence, creation and evolution, the divine and the human, the spiritual and the earthly are all different ways of pointing at a deep divide between minds trying to understand the source of all being and how they are related. Great religious wars have been fought and continue to be fought over these different belief systems. Chinmoyee and Mrinmoyee have not been reconciled for good yet. That does not mean, however, that they cannot be seen differently, as being related in a harmony that is not just possible, but inevitable.

Kazi Nazrul Islam (1899 – 1976), a 20th century Bengali poet noted for composing several moving devotional songs dedicated to Goddess Kali and Lord Krishna, is caught in one of his songs struggling to fathom the gap between Chinmoyee and Mrinmoyee. He beseeches the divine mother to come to him in her Chinmoyee form. He thinks our woes are attributable to the worship of the mother in her Mrinmoyee form. He then proceeds to describe the great divine energy or Shakti as that which can never be submerged, that which is ever manifest within us and in the world outside us, that which cannot be kept confined in temples or fortresses. Clearly, he is not seeing the spirit as residing in the image of the goddess and his whole being yearns for a rendezvous with a different kind of being, a spiritual entity that is beyond the goddess as enshrined in a material, finite form. Deprived of the devotion placed in her by the devotee, the image turns into a lifeless, meaningless idol. Mrinmoyee becomes a mere clay toy, finite, mortal, impermanent, subject to time, with a beginning and an end, unable to deliver spiritual fulfillment. Chinmoyee on the other hand, is consciousness pure and simple, infinite, eternal, a source of bliss and power that never fades. Nazrul is trying to make some ultimate distinctions in order to bring order into his house put into disarray by conflicting, undefined thoughts. He feels the need to classify, categorize and arrange things according to their types—clothes in the closet, books in the shelf, food in the pantry etc. It is hard to comprehend the world and our place in it without making an effort to settle the dust raised by confusion in understanding. The first step towards sanity would appear to lie in making distinctions and understanding the nature of such distinctions (Kazi Nazrul Islam, 1996).

In this context I would like to discuss some notions with which the philosopher G.E.Moore played in his book *Some Main Problems of Philosophy* (Moore, 1966). In the first chapter of his book Moore begins by offering a definition of philosophy as "a general description of the *whole* of the universe" (p.13). Philosophers, he maintains, must mention all the significant things they *know* are in it and also how these are related to one another. He then proceeds cautiously by trying to compare philosophy with "Common Sense", mentioning that philosophers venture beyond the opinions of Common Sense, sometimes even contradicting Common Sense. Common Sense believes there are ultimately two different kinds of being in the universe, namely, material objects, which have no consciousness, and minds, which can perform conscious acts. All material objects are thought to be in space and can be understood to be related to one another by means of directions and measurements. Common Sense further tends to believe that all minds or acts of consciousness are related to some material objects in the sense of being rooted in or "attached to" them in the sense that when we engage in mental activities, those acts occur "*in the same places* in which our bodies are" (p. 19).

Material objects, however, can exist independently of consciousness. There was a time long, long ago, when there were only material objects and such a time can come again in the future with conscious acts wiped away from the scene in the course of Nature. This underlines the fact that Common Sense believes both material objects and conscious acts to be in time as well as in space. Past, present and future are legitimate terms in which they can be understood. Common Sense does not usually deny that theories about facts can change, can be proven to be wrong or right as time progresses. But these are only admitting changes in our "knowledge" of things. How far is Common Sense willing to go to admit changes in the things themselves? Will it admit that matter can evolve into consciousness and that this can happen due to an inward unstoppable force in matter to become something else? Common Sense is reluctant to venture into the world of "possibilities". But in all good faith, it cannot deny that there is a world of possibilities. Common Sense, however, does not have to go into such a world because it is not committed to give a description of the "whole universe". That is the philosopher's task. Common Sense is content to maintain the orderliness of its house as a more or less closed square of solid lines in which there are basically two residents, mind and matter, with mind dependent on matter and matter capable of existing independently of mind.

The philosopher's square, on the other hand, is made up of dotted lines. This square has to be ready to admit the "possibles" to freely go in and out of the realm of the world it is trying to give shape to. If philosophers have to go with the two ultimate distinctions in the universe as being matter and mind, then in order to treat this picture as a general description of the whole universe, the philosopher will have to say that all that there is must be either matter or mind, or else the modified statement will have to be that all that we *know* to be in the Universe is either an act of consciousness or a material object, though "there *may* be in the Universe other things which we do not know to be in it." (Moore, 1966, p. 27) There are many other kinds of things in the universe that are unknown to us and may possibly never be known. The limits of our knowledge are *known* to us and therefore have to be included in a general description of all the significant things in the universe. It would be unphilosophical, a-logical and unscientific to exclude the realm of the possibles from a general description of the whole universe, both theoretically and empirically. Moore feels that besides the entities in the unknown worlds, there are things within our known world that cannot properly be described as either material objects or acts of consciousness, for instance, space and time or a divine being and how it is related to material objects and conscious objects. A philosopher must therefore always maintain an open outlook and not give in to the urge to arrive at ultimate and irreducible distinctions between kinds of things, thus allowing for transitions from one kind to another, imperceptible and catastrophic change, gradual growth, manifestation of pre-existing conditions and emergence of novelties in the universe. Seeing fixed order and neatness where there is constant change and transformation is being untrue to the self that is seeking knowledge. There may very well be something that survives change or maintains continuity throughout the change, is fashioned and refashioned as a rejuvenated being. During the process, however, there are blurs, losses, gains that are in play. The path of nature proceeds through apparent confusions and demolition of set lines of distinctions to a continuous process of creations. Chinmoyee and Mrinmoyee may not be two distinct ways to contemplate the creative energy. The two may mingle, separate, and reunite endlessly in the world of thought as well as in nature. Not admitting this may have been the reason behind Nazrul's woes, not the preoccupation with Mrinmoyee as opposed to Chinmoyee.

A discussion of the feasibility of ultimate distinctions between beings cannot be undertaken without trying to understand what indeed is being. What exactly do we mean when we say that something has being, that it *is?*

Does it mean that it is out there, to be seen, to be talked about or experienced in some way? But then is it not there even when we do not relate to it in any way? Some may think that that indeed is what being is, that it is there even when it is not entertained by us in any way. That we can come back and find it as it was confirms and verifies its being-hood. What if we find it altered in some way upon return? It still is, differently, but has not lost its 'isness'. What if we find it missing? It may still be somewhere else? It can definitely be in my mind, my memory, my imagination. What if it has been trashed, smashed, thrown out, removed, altered beyond recognition? Like a junkyard car or the ashes of a cremated dead body scattered into the air or the oceans? It still is somewhere, in some shape or form. It has lost its specific form, structure or chemical formula that enabled it to perform specific functions, but it has acquired newer such things and is performing different functions. Perhaps that is the best way to understand being, in terms of what it can do, do better or do differently; in terms of what it is no longer and what it is now or can become. Being is best understood in the context of non-being and becoming. Becoming does not have to deny the existence of continuity. Even if that which changes itself undergoes change it may still be possible that the outcome of the change was contained in that which gave birth to the new. In the acorn and the oak tree or the chicken and the egg controversy, the oak and the chicken are there first to make the acorn and the egg possible.

Thus, not only is continuity of being possible amidst change and new birth, not only can being not be understood apart from change, but being is impossible to comprehend without reference to its form, its structure, its function, its connection to other beings serving other functions, its inter-connected operativeness in space and time.

At this point it becomes imperative to take a look at Aristotle. For the purpose of bringing in Aristotle, I will use the text *Aristotle*, by John H. Randall (1960). Aristotle's Metaphysics, which started out as being the Science of Divine Things, later became his First Philosophy, in which he explored the nature of anything that is. He endeavored to figure out what is involved in just being. In the world of logic, to be means it can be made the subject of some kind of discourse. We should be able to ask questions about it and be able to get answers to those questions. In the existential world, to be means to be part of a process. A process is going from one state to another state, but the passage does not occur from a sheer absence of something to becoming another thing. The journey from A to B means that A had the capacity to acquire the properties of B and achieve them in the end. Things sort of have a "career" to develop. They are always trying to attain what they are potentially capable of. Aristotle talks about three factors at play in all processes of change that are going on in nature. First there is the subject which changes or the material that changes. Second, there is that, what it is changed from, carrying within it the absence and yet the potentiality of that into which it is going to change. Third, there is the form that the thing acquires as it changes. Things that are said to happen by chance may appear to be unpredictable, but they are not inexplicable. They may appear unrelated in a causal chain, but each one of the minute links between the events that are apparently unrelated but yet together can produce a startling impact or event, are actually propelled by reasons of their own and their combined interaction goes forth to produce an effect that may look like a significant event which came about by sheer chance or accident. When the generation of the new is achieved, the old still continues to live in the new, but not in the same ratio and proportion as the formula for the emergence of the new needs. They continue there as further potentialities.

Aristotle thus saw Nature as a great dynamic process in which things were continually passing from the power to be to the actualization of the power, to the actual functioning of that power. He further believed that each thing had its own specific function determined by its own structure. He did not think that matter could exist in an indeterminate, generalized form. To be was to be in form and to strive to bring into further form all that it was capable of generating, given the specific circumstances in the environment, in the other things surrounding it with which it was in constant, inevitable interaction. Everything harbored within it a bubbling energy, an inherent tendency to spill out in action and give rise to newer forms with newer functions. The powers contained within each thing, as determined by its material and form must find expression, must move forward in Nature's process of creation. Aristotle called this bursting, impelling energy *horme*. Everything continually moves towards becoming different. Being is never static, never indeterminate.

Also of significance is Aristotle's notion that beings are active not just due to their own inherent and unstoppable principle of motion surging within them. They are also in motion because of the impact they cause on each other in the environment. It is as though if we learned to the fullest depth possible in knowledge about any one particular thing, we would thereby come to know about the existence and nature of all other entities in the world. Each thing is thus a mirror of the world. Aristotle was a pluralist, a dynamicist, against any ultimate distinction possible between matter and consciousness, against the possibility of matter without form and the actual being of form without matter in a realm outside of logic. In the existential world what we encounter is always matter in conjunction with particularized form, endowed with specific powers to realize itself further, in constant action, forging ahead in the creative activity that is Nature. Chinmoyee thus could exist in Aristotle's view only as a cognitive principle, simply as a noun that referred to the idea of consciousness. The moment it laid claim to have being that we can actively interact with, it acquired form. In fact, it is not intelligible why even logical principles can be said to be untrapped in some kind of form. A noun is a form of understanding. After all, are they not constructs or presuppositions that are born in the human brain due to the way the brain is programmed to think? Is logic not a product or way of functioning of our brain and are these cognitive principles not applied to understand the existential world? It is understandable that they may be differentiated from the world of form and matter, but do they have any ontological claims beyond their place in the world of human discourse?

One must also reckon that Aristotle further believed that to be is not simply becoming something different and new, but that to be is also to pass away. The 'this-object dies when it becomes the that-object' in the sense that its form becomes different, its functions become different. The elements remain in the next object, but combined in a different formula, performing different functions. In this sense, there is immortality in being. The new tides carry along in their waters the same water but each sprawl of the water, each one of its waves, each one of their sea-borne treasures are different. The ashes of our cremated bodies sink to the river-bed and bear aquatic plants that feed the fish that feed us. The air carries the ashes to distant mountains and deserts, to fertile valleys, become a part of their landscapes and their specific operations. The same thing happens when we bury the body. In time it becomes a part of mother earth, a source of nutrition for Nature's wealth of plant and insect life, ultimately becoming a part of us. So being never becomes nothingness. It changes form and function, emerging from one motion to another. There never was a time when there was no motion. Motion never began, nor will it ever cease. Therefore, if to be is to be in motion, then there never was a time when there was no being and there never will be a time when being will cease to be. There is no other eternity than the ceaselessness of motion and being.

Is all this unceasing generation of the new a change towards the *better*? Change does not necessarily mean progress.

First of all, when we try to interpret change as progress or the opposite of it, we have to use standards that are relevant to the specific judges or the subjects that we judge. What is a mark of progress for the human world may be destructive for the survival of other species and the environment. Since Nature is an intricate web of mutually dependent organisms and all other natural processes or beings, no single change can be ultimately voted to be progressive without reservations, without being very tentative and cautious. Keeping this possibility in mind, can we still discern in the processes of nature a direction towards something better, not just something different?

It would appear that what would be judged better for any being would be its ability to survive and thrive, to perform its function more and more perfectly. Reproduction by two parents opens up this path. Reproduction and survival of the young become the main thrust of all physical-chemical-biological processes. Responses to stimuli are geared towards these ends of survival. Unsuccessful responses get discarded and those that promote survival stay on and get drawn into the game.

So is nature teleological? Aristotle's natural philosophy has been described as a theory of internal teleology in the sense that every object is internally propelled to fulfill the potential into the actual being. Is this inherent necessity behind motion to become different purely mechanical? Or does what goes on within a being during the processes of becoming have the basic building blocks of activities that attain goals or ends by the following some means? Aristotle is well-known for his four causes. The formal cause or the vision of the thing to be, the end for the actualization of which the process is in place, is the purpose which guides the entire process of production. This formal cause operates in a capacity that can have a great range. In some cases it can be described as unconscious, but consciousness itself is a matter of degree. What goes on inside a seed is different from what goes on behind the formation of a canyon, but how different and in what ways different? Even some of our most significant decisions may be arrived at without exercising much intelligent deliberations. We all know about the instinctive activities of birds and bees that are performed in the middle range between the totally unconscious and fully conscious. The exercise of consciousness is not a necessary condition of processes that achieve ends. All machines, whether hand-driven or automatic, achieve ends by means. Hence Aristotle can without difficulty say that all processes of nature are purposive. They show the marks of certain means being used to achieve certain ends as directed by their specific structure. The fact that in each set of activity the operation of these means and ends follows a *regular* pattern, as though one step is leading to the next, is what prompts Aristotle to suggest that nature moves with a purpose.

The temporal order of sequences between these steps is such that those steps must be followed in order for the outcome to be achieved. In Nature, the succession of events is not such that any moment in time can be followed by any other moment. Moments are connected by an internal connection of necessity in order to become the next thing in the process. This is the Aristotelian necessity. It can be viewed as blind or fully conscious depending upon the field of operation or the stages in the life of a being. Wherever the presence of what we understand as the rudiments of life and consciousness are detected, the change is easily observed and understood to be mostly productive, for the better, boosting the survival value of the thing. As for the energies in motion in what for the lack of a better word, I would say, the pool of potential energies, the upheaval and succession of steps is not accidental at all either. Each emergent is conditioned to arise in order to proceed to the next step in an endless series of experimentations to try out and bring forth newer and newer forms which will allow more and more perfected operations of their functions. Life and consciousness are born and set on a survival mode as a result of these ceaseless changes going on in the energy filled core of being. To understand their emergence may be we need to rethink life and mind.

In a public release made on January 4, 2016, by the University of Groningen, the Netherlands, the release item entitled *The Origins of Abiotic Species* published in the journal Nature Chemistry (Sadownik, J. W., Mattia, E., Nowak, P. and Otto, S., 2016) report some very interesting research work done on how life may have evolved from chemical processes. Experiments were done to determine if the two basic processes of living organisms, namely, replication or autocatalysis and self-organization whereby organisms spontaneously develop themselves into higher order structures, can be detected at the molecular level. Sijbren Otto, the university's chemistry professor and his research group not only developed self-replicating molecules but also observed diversification powers in the replicator mutants, with a second set branching off spontaneously from an ancestral set of replicator mutants. Otto reports that first they had found that some small peptides could arrange themselves into rings. They then found that these rings could form stacks. Once the stack formation began, it would continue to grow and then break into two smaller stacks. Then the smaller stacks would both grow and further break into smaller stacks. The process would continue, with the stacks stimulating the formation of rings that compose them. These rings and stacks have been designated replicators as they are basically making copies of themselves.

Following this, Jan Sadownik, a researcher in the group, discovered that if the replicators are fed two different types of building blocks, A and B, then a set of replicator mutants will emerge that specialized in A and also contain some B. A few days later a second set of mutants emerged that specialized in B but also tolerated some A. This second set descended from the first set, and thus was like a grandchild to the original mutant group. The diversification process was displaying the structures of heredity or ancestral lineage. This was also akin to how new species form out of existing species, the process underlying biological diversity in nature, the exception being these processes were all occurring not at the full-fledged biological level but at the molecular level instead. Hence the process has been aptly described as *molecular speciation*.

The researchers experimented with the death of these sets as well. They channeled a stream of building blocks into the system to feed the sets while at the same time draining the contents of the reaction container. Only those replicators survived whose growth rate surpassed the removal rate. If the environment was changed by introducing another solvent, that would impact the fitness of the different replicator mutants differently. The mutants would then move towards those that are best at replicating themselves.

It is certainly possible to see some of Darwin’s natural selection at work here. However, the mutants appear to be working less out of chance, but more as driven by some kind of inner necessity towards survival and attainment of the higher order promoting survival. Aristotle would have been delighted to participate in this research which brings us face to face with processes of evolution, baring the palpitations of life in molecules and advancing towards greater and greater complexity. The links between Mrinmoyee and Chinmoyee, the earthen and the pinnacle of consciousness are also found here.

Tim Requarth who has his PhD in neuroscience from Columbia University, where he also taught biology, chemistry, and science writing and who currently directs NeuWrite (http://www.neuwrite.org/), a national network of collaborative working groups for scientists and writers, writes in the article Our Chemical Eden (Requarth, 2016), about the discoveries of the famed geologist Mike Russell or Professor Michael J Russell of NASA, JPL (Jet Propulsion Lab.), Pasadena, California. He writes that Russell’s first intuition into how life came to be occurred when he happened to inspect a shattered toy of his son. It was a tank which was like a chemical garden in which tendrils of rocks grew in a chemical solution. When the tank broke Russell found that these rocks were really hollow in the inside, like a bunch of drinking straws. Russell was working at the time at similar rock formations as part of his geological work. When he saw the formations in his son’s toy, the thought suddenly flashed in his mind that his rocks too may have formed in some such unusual chemical solution. He struck the hypothesis that undersea hydrothermal hot-springs through which mineral rich water ejected out of the earth’s belly, subsequently precipitating in the cool ocean waters, gave rise to the chemical gardens of the hollow rocks. From this hypothesis he took his second intuitive leap by positing that life originated in the wombs of these hollow rocks, in the warm chemical pools they cradled. Behind Russell’s intuitive conviction was his belief that he had found the energy that life mobilizes to grow and replicate. To him, the energy and the life using the energy no longer appeared to be two different things, but one and the same force. It did not take his geologist’s mind long to realize that such undersea chemical gardens would be sources of plentiful material energy trapped locally and fit for the emergence of self-replicating systems. In fact, given the set of conditions there, Russell believed that the emergence of self-replicating systems was not just possible, but inevitable. Life appeared following the same principles as galaxies were formed or tornadoes happen: Given the set of necessary conditions as they exist in the chemical garden, life will invariably emerge.

Russell thinks that the chemical gardens provide a natural environment for the emergence of what is known as chemiosmosis which is an essential process for the generation of energy needed for the living body. The mitochondria of the cells draw the chemical energy from food and convert it into the molecule ATP with the help of oxygen. ATP is the molecule of life. It is the energy we use every moment of our lives in whatever we do, consuming about 10 million molecules of ATP every single second. Energy flows through the mitochondria through a chain of proteins consisting of thousands of atoms. The protein chain traps the high energy electrons and passes them down the chain. The movement of the electrons creates an electric current which in turn traps a great many number of protons between the inner and outer membranes of the mitochondria. These protons can escape only through what is called ATP synthase, a special protein. This intricate machine spins like a water-wheel hundreds of times per second and protons falls through it as in a waterfall. Russell thinks that the early oceans were likely acidic with a high concentration of protons. However, the water coming up through the hydrothermal vents is alkaline with fewer protons.

Russell conjectures that this difference created a natural proton waterfall from the ocean to the undersea rocks which were thus filled with these protons. The proton flow and the electron transfers created simple reactions. Then as proteins evolved, some cells produced a primitive form of ATP synthase. While the ATP synthase is the same in every organism that is, the protein chain that traps protons is not so. This means that the first organisms used an existing proton gradient before they developed the means to create their own. In the rocks of the chemical gardens the proton gradients took shape. Life did not just happen. In the nooks and crannies of the rocks the carbon dioxide in the ocean reacted with the hydrogen from the earth's vents. This reaction took place due to the minerals iron and sulfur in the rock's walls. Small organic molecules came into being as a result of these reactions, such as the acetyl-CoA, one of the oldest. The molecules linked up to each other in the temperature gradient with cooler temperature on the outside and a warmer one on the inside. This created the connective process known as *thermophoresis*, which traps the molecules in compartments and leads to the formation of sugars, amino-acids, lipids and nucleotides which are the building blocks of life. Russell concludes that given the conditions of intense temperature and pressure under the seas, the building blocks were inevitably produced and further connected to bring into being more complex molecules. Genetic structures began to take shape and passed from one rock nook to another through micropores, thus colonizing stretches of rock territories and giving birth to the first cells.

In 2000, the vessel Argo II was lowered into the Atlantic to survey an underwater mountain range. It went past the depths reached by sunlight, past the half-mile mark of the gauge. Then came the startling revelation by the vessel's lamps. Peaks of rocks as tall as buildings twenty stories high rose out of the ocean bed. Heated water boomed out of them in gleaming spouts. A host of aquatic life flooded the region nourished by microbes that can convert raw elements from the inner earth without the sun's rays. The field was named The Lost City and it confirmed Russell's prediction of the chemical garden.

Do these theories of the origin of life go against the Second Law of Thermodynamics or Entropy which state that the universe is headed towards disorder from order? First of all, order and disorder are perceived by just human beings and they may not exist in anyone else's world. So this description of the trip is to be understood with expressed modesty. We can see the "this" or "that" in the path of the universe as conditioned by the equipment we are endowed with; or this or that principle is a logically necessary supposition to explain our observations or to put things in place coherently but we should be very cautious before we claim that the way we explain the world, whether empirically or logically, has any meaning beyond human discourse. This acknowledgement of relativity is the minimum humility required of any thinker. However, being who we are, our adventures into knowledge must continue. Theories must abide in coherence with each other and must be supported by newer knowledge gained. This is what Moore affirmed when he contended that the *whole* universe must allow room for possibles. Aristotle tried to explain generation by both theory (by positing an Unmoved Mover and *horme*) and practical observations of inner necessity between means and ends making what is potential into an actual being. Otto, Sadownik and Michael J. Russell's work shed light on how life may be understood as a stage in the life of the flow/cycle of energy we know the universe to be.

If we are content to say that the stages that mark the appearance or presence of life and consciousness show more complexity, more necessary connection, more means and ends kind of relationship, more self-replication and self-organization capabilities than are observable in the preceding stages, then we can come forward to share our belief that as far as we know, nature shows signs of orderly development, where one step leads to the next, where things do not happen by chance.

If life is understood as flow of energy then the story of life goes as far back as the Big Bang. Russell felt that the Big Bang generated a stress so great that it could be dissipated only by forming structured systems that came to be and then passed on to become something else. If the Big Bang led to an even distribution of matter and energy then nothing further could have happened. No further dynamism would have been noticed. But things are understood to have happened differently. It is likely that quantum fluctuations in the structure of space made a balanced distribution of matter and energy not possible. Instead structures arose, particles grouped together and were bound by gravity, leaving vast expanses of space that remained somewhat empty. Collapsing structures formed stars, gas and star-dust formed into planets with red-hot bellies given to tectonic shifts and volcanic activities. Hydrothermal vent structures opened up, creating in our earth the requisite temperature gradient in the chemical garden that further translated into life. Such a sequence of events cannot be ruled out elsewhere in the universe, now or before or in the future, given the limited scope of our knowledge and the limitlessness of what is out there. But the important thing is that we *know* of this situation.

Thus Russell[2] combats the view that his theory of the origin of life contradicted Entropy by asserting that the appearance of life is not a disorder to order movement but rather an "order from

---

[2] Note: Russell was the 2009 Award Recipient of the William Smith Medal of the Geological society of London. Here is an introduction to Russell at the Award Ceremony:

William Smith Medal – Prof. Michael J Russell (NASA; JPL)

> The medal named for the Father of English Geology, William Smith, was first awarded in 1977 and is given in recognition of excellent contributions to applied and economic aspects of geology. It is therefore particularly apt that this year the medal goes to Professor Michael John Russell, now of the NASA Jet Propulsion Laboratory, Pasadena. For over 20 years, Mike Russell was Professor of Applied Geology, first at the University of Strathclyde, then at the University of Glasgow. As befits someone whose original contribution has lain mainly in our understanding of mineral deposit geology, Mike began his career working in industry and surveys across the world; but his subsequent research concentrated on the giant Irish Carboniferous-hosted base metal ore field – still Europe's biggest zinc producer and the world's most concentrated zinc source. In a period when the demands on metal resources are increasing and stocks being depleted, Mike's work is all the more important. In addition to developing the use of trace-element haloes as an exploration method, Mike linked ore genesis to the emerging theory of plate tectonics, developing original theories about north-south geo fractures that continue to tantalize explorationists. Mike Russell is one of our science's truly original

order" process. Without the presence (or perception thereof) of an initial order, no further organization can take place. Geological complexity is the necessary precedent of biological complexity. To him, life is best defined not in terms of what it is but what it does. It is a way of being in constant passing from this to that while yet maintaining ancestral link.

In Chapter XXI of Life Divine, philosopher Sri Aurobindo Ghosh (2005) dwells on the Ascent of Life. He tries to distinguish between four stages in the evolution of life much of which appears to fall in line with the works of Sadownik et. al. (2016). In the first stage, matter expresses itself as moving towards life by means of division. In the second stage comes aggregation. In the third stage comes mind or the desire to unite with fellow beings to make aggregation a reality, to preserve and make permanent, by heredity on the physical level and aggregate memory on the socio-cultural level, what the processes of division and fusion have achieved, what the individual being has experienced in its life-span and what will otherwise, but for the emergence of this level, be lost forever. The survival value of this third stage is enormous. But for Aurobindo, the fourth stage, which is the emergence of a higher form of mind, is even more important. The fourth stage consists in laying a *conscious foundation* for our vision of harmony with the whole universe upon the discovered unity and link between our body and the rest of the bodies, our life and the rest of the lives, our values and those of the others (Sri Aurobindo, 2015). This is the point where the scientist, the philosopher and the saint join hands. Neither the scientist nor the philosopher, nor even the saintly person can choose to ignore this question: How am I going to conduct myself in relation to all that is, was and will be and what is the reason behind my choice? To answer this question satisfactorily one must know how life came to be, how it diversifies, how it is preserved and how it progresses further.

This makes it necessary for me to examine what Bertrand Russell (1963) had proposed in his book *Mysticism and Logic* regarding the use of the scientific method in philosophy. The noted mathematical logician who is also acclaimed as a great philosopher of modern times had his own model for philosophy. He believed that meddling in ethics and religion have largely been not beneficial for philosophy, that it should turn to science instead for successful pursuit. In Chapter VI (entitled On Scientific Method in Philosophy) of his above referenced book, he says that philosophy can find science useful in its domain in two different ways. It can either base itself on the results of science, or it can apply the methods of science in its own investigations. Next he gives his considered opinion that philosophy can gain more from employing the scientific method than from the specific results arrived at by the different scientific researches. He says that philosophers, particularly evolutionary philosophers, often tend to give an air of absoluteness to empirical generalizations based upon observations and proceed thenceforward to describe evolutionary change as "progress" whereas decay is as much a phenomenon of nature as growth. The essence of the scientific mindset, according to Bertrand Russell, is to remain receptive to facts. While philosophers may remain cognizant of the results of the specific sciences in order to stay educated, these results do not impact the essential nature of the philosopher's business. He gives two reasons for this. He says that a philosophical proposition must not be regarding such properties of things that just happen to be. They should be such that they are true of any possible world

---

thinkers. His work on ore body generation led him into the debate over where life originated. His idea about hot deep spring environments as a hatchery for the first proto-living organisms has now moved centre stage, and its clear astrobiological implications are what led to his current appointment at JPL.

independently of verification by the senses. This leads Bertrand Russell to his second statement that a philosophical proposition must be a priori or “such that can be neither proved nor disproved by empirical evidence” (Russell, 1963, p. 84). He proceeds to characterize philosophy as “the science of the possible” and hence as indistinguishable from logic. Analysis, and not synthesis is the job of philosophy. When philosophers veer from this role and start interpreting the results of science and offering rosy and optimistic pictures of the universe and evolution, they are guilty of giving “legislative force to their own wishes” (p. 82).

In Chapter I of *Mysticism and Logic*, Bertrand Russell comes down hard upon the tendency of the philosopher to anthropomorphize and be a preacher of “pleasing dreams” (p. 29). The philosopher, he says, needs to maintain “ethical neutrality” (p. 29). A philosopher should have nothing to say about pessimism or optimism, good or bad, love or hate. There is not enough abstract difference between these ethical opposites. There is not much difference that is substantial between them, not any difference of form or structure, the opposites being very similar to each other in being simply states of mind. Philosophers should be more interested in knowledge for its own sake and

> acquire the disinterested intellectual curiosity which characterizes the genuine man of science. Philosophy is not a short cut to the same kind of results as those of the other sciences: if it is to be a genuine study, it must have a province of its own, and aim at results which the other sciences can neither prove nor disprove. (p. 25)

It appears that Bertrand Russell has taken upon himself the task of defining philosophy. By adopting his definition, we would have to exclude many great philosophers from their entitlements. I agree that anthropomorphism is always a lurking danger for us, but would consider that even Bertrand Russell is guilty of that slip when he states that a philosophical proposition has to be true of all possible worlds. Logic is but a tool of the human mind. Its propositions are but *our* ways of understanding. The only way to avoid being anthropomorphic is to remain aware that our knowledge is always going to be through the human lenses but I refuse to narrow down philosophy to this single statement of the relativity of human knowledge. Socrates was humble but that did not stop him from raising crucial social, moral, political and epistemological questions. Philosophers must not quit interpretation of data and sharing their pursuits with scientists and moral, political and religious philosophers. They are all philosophers in their own rights inasmuch as they are all trying to fit pieces of puzzles which cannot be put together without mutual corroboration. It is true that knowledge is increasingly becoming specialized but no one can dictate that they must remain compartmentalized, that the findings of one branch cannot be shared with another, commented upon and absorbed in a common field. Philosophy is what it etymologically is: love of wisdom. Knowledge becomes wisdom only by interpretation and wisdom becomes enshrined in us only through internalization and constant practice. Philosophy has to be what we deeply believe in, and as such it holds hands with religion, ethics and politics. It must not be forgotten that Socrates, Christ, Meerabai, Gandhi, Martin Luther King Jr., all five of them gave their lives for what they *knew* and *believed* in, and there have been many others who go unnamed, here and in history books. The five named here lived their lives by their *philosophies* which they arrived at by intense cognitive and living soul searches, by means of countless interactions with other beings. If they are not to be admitted as philosophers, the claim of Bertrand Russell to be counted as one will remain in the shadow. Ethical neutrality is a most unbecoming feature in any human being, and more so than tendencies to hasty generalizations and forgetting to submit to facts. The latter two can be more readily corrected while the first represents an attitude, a conviction, much harder to overcome. While it is good to rein in baseless optimism, it is important to have faith and the nurturing of faith is sustained by the admission of the world of possibles. Faith generates hope and courage. However, if it does not make us love and teach us to live in harmony, then such knowledge of possibles is of no use. We can be logicians only when we have learned to live and survive. It is my philosophy that a prosperous garden can be cultivated by scientists and philosophers of all shades when they draw upon each other.

Not only are abstractions envisioned and formulated by human beings, they are derived from our experience of particulars, fed by our interactions with and thoughts about particulars and are seen as applicable to particulars. The first question that is put to a suspect in a murder case is: Where were you at the time of the murder? The implication is that someone cannot be in two places at the same time. If the suspect was at a restaurant at the time the murder took place in a home, then the district attorney has a problem. Anybody who is trying to shear the bond between the universal and the particular, the abstract and the concrete, change and continuity, the one and the many, spirit and matter, the divine and the earthly, consciousness and the life and energy flowing through the world is doing us a big disservice. If we cannot see these supposed opposites as residing in each other, if we fail to recognize Chinmoyee in Mrinmoyee and Mrinmoyee in Chinmoyee, we will continue to hurt the earthly woman while singing praises to the goddess's divine nature; or ignore a child's well-being while putting the child Krishna and baby Jesus on pedestals. This is my opinion, based upon knowledge derived from the humanities and sciences, and yes, I am philosophizing when I am saying this. My philosophy is my belief system and network of actions *consciously founded* upon my knowledge as it is today. This conscious foundation-laying is what makes me and anyone else a citizen of what Aurobindo referred to as the world of the Supermind. It is also what determines my path, helps me stay on the path and serves as justification for why I do what I do.

It is important to understand that divisions, distinctions, and contrasts are useful mostly for analytical and artistic purposes. If they make us blind to fusions and create in us the inability to see the whole picture, then we are being deprived of seeing the way Nature works. There are no clear-cut distinctions in Nature. The living is in the dead, the dead is in the living. Spirit is in the dust and dust is in the spirit. Resistance to see ourselves in each other is what leads to wars; obliviousness to our ties to Nature, animate and inanimate, is what leads to cruelty to animals and environmental disregard. Likewise, failing to see Chinmoyee in Mrinmoyee is what leads to the ridicule of images as idols, to hate wars against image-worshippers.

To further understand Mrinmoyee it is imperative that we gain an insight into what is involved in the process of image worshipping. An image can be understood in different ways. It can mean a reflection, as in a mirror or in water. In such circumstances it is easy to bear in mind that the image is not real in the same sense as the object casting its reflection. When Sultan Alauddin Khilji[3] was allowed to behold queen Padmini's image in the mirror by her husband, the sultan knew the difference. The situation was different with the lion in the Aesop's Fables. The lion jumped to its death in rage upon seeing its image in well water because it took the image to be real. Similarly, the men in the allegory of the cave in Plato's Republic thought the reflections cast on the cave wall to be the real objects because they were forever enchained and could never turn back to cast their eyes on the real things that were casting the shadows, exemplifying the classic principle of *maya* or ignorance rooted in the human condition which can be undone only by conscious effort or divine grace resulting in enlightened perception. In worshipping an image, the worshipper does not consider the image to be a reflection of something else that is more real as in the case of Padmini and her image. Nor is the devotee trapped in a state of ignorance or illusion from which there is need of deliverance. The worship is offered not to an appearance but to what is considered to be the real thing by the devotee.

---

[3] Alauddin Khilji was the second ruler of the Khilji dynasty in India reigning from 1296 to 1316. A tale of his attack on Chittor in 1303 CE to capture the queen of Chittor, Rani Padmini, the wife of Rawal Ratan Singh and the subsequent story have been recounted in the epic poem Padmavat, written by Malik Muhammad Jayasi in 1540.

Image worship is also significantly different from belief in pantheism and immanence. If the divine is believed to be everywhere then a stone, a tree, an animal or every conceivable form is worship-worthy. But this is not the reason why a devotee showers all his affection on an image. The philosophy of immanence simply serves as a justification for the idea that there is nothing impious about a form, any form. Ushering in *Mrinmoyee* has more to do with "manifestation". An image is worshipped because the devotee considers that the deity is manifested in the image. Such consideration by the devotee is a very conscious process involving deliberation and choice. The worshipper has to ritually instill life into the image. This process is known as *pran-pratistha*. The process can also be undone and the deity bade good-bye as in the practice of *Visarjana* or immersion of *Mrinmoyee* or the clay-image in water. In an act of worship, the worshipper plays as important a role as the object of worship. The worshipper calls upon the deity to be seated in the image and then engages in interaction with it. An example would be the Wilson volleyball from the Tom Hanks movie Castaway.

At the other end of the road of worship is the worshipped. While undergoing the process of manifestation at the call of the devotee, the deity becomes subject to all the limits of form, including birth, growth and death. The thought of such willing submission to limits in order to answer the devotee's call is seen as proof of the abounding love of the creator for the created. The belief in incarnation is closely related to the contemplation of godhood as Mrinmoyee, the earthly one, the one of flesh and blood, the manifest fountainhead of all that is treasured in *chit* or consciousness.

The separation of *Chinmoyee* and *Mrinmoyee* is, in the ultimate analysis, untenable. Nature is a continuum and is worship-worthy as such.

Jonathan Reams[1]

Welcome to this issue of *Integral Review (IR)*! We are pleased to welcome you to a new regular issue, which brings together a number of interesting articles, essays and reviews.

It has been a while since our last regular issue in January of 2016. While we are pleased to be able to publish a range of special issues over time, we are always excited when we are able to pull together a new regular issue. These issues are a long journey, through many different kinds of processes for the authors, reviewers and editors involved. Despite these differences, all of the contributions in this issue can be perceived as forms of advancing our understanding of an integral view of the world and our participation in it.

If I was to look for a theme in this collection of articles, essays and reviews, I would say that it has to do with understanding consciousness and how it shapes our existence and experience in this world. 40 years ago I began my university education studying physics, but dropped out and later turned to studying consciousness (and leadership). Along the way I have encountered numerous perspectives on the relationship between the two subjects, with a polarity in perspectives, from materialist interpretations to idealist ones. This conversation continues today, being taken more and more seriously as it becomes apparent that we cannot ignore an integral view of the intimately intertwined nature of consciousness and matter. The science magazine Nature recently highlighted this as an ongoing conundrum (see article here). An example of an integrative perspective comes in the notion of panpsychism, that consciousness is a fundamental feature of physical matter, which is being taken seriously by a wider range of mainstream physicists and others (see article here). All of this leads into the territory IR has always been intended to serve as a platform for new thinking from an integral view.

Thus we fittingly begin this issue with Doug Marman's *The Lenses of Perception Interpretation of Quantum Mechanics*. At IR, we are always on the lookout for new thought and Marman delivers on this. His article is a substantive piece of investigation into some of the most fundamental questions science has ever tried to answer. In true transdisciplinary fashion, Marman covers a wide range of disciplinary knowledge. He begins by showing similarities between quanta and living organisms, leading to an inescapable predication that quantum behaviour is driven by sentience. This leads naturally into a detailed examination of consciousness itself and how participation is a creative process of perception. (This is something that will also show up in Bonnitta Roy's article). Marman then lays out a set of nine postulates that lay a more formal foundation to show how his Lenses of Perception interpretation can address a wide ranging and essential set of issues generally held as necessary for any theory to be able to bring coherence to our understanding of all physical

processes. Having done this, an examination of quantum formalism and how the LoP interpretation (using first, second and third person lenses) not only meets the tests of quantum formalism, but even shows why the second person lens of relationship is necessary for understanding it. Finally, Marman lays out how his LoP interpretation meets a variety of challenges, including the five unsolved problems of physics, and points to ways to test out this interpretation. The overall scope, depth, breadth and rigor of Marman's work makes this article a seminal contribution to discourse around these fundamental questions, and IR is pleased to publish it here.

We follow this by diving into the application of how consciousness shapes organizational and leadership culture, and what can be done to support its healthy evolution. John McGuire and Charles Palus, both senior fellows, long time faculty and researchers at the Center for Creative Leadership, bring us an article on *Vertical Transformation of Leadership Culture*. They tackle one of the most challenging topics in leadership and organizational theory, that of culture. They approach it by linking their work in development theory with the DAC framework (direction, alignment, commitment), a relational ontology and process model of leadership. This link enables them to clearly describe and indicate how to work with leadership culture in a manner that enables transformation. This work has led to the creation of tools that are elegantly simple to use, yet naturally stimulate the kind of reflection that promotes growth (speaking from the experience of not only using some of these tools, but seeing others use them successfully with no knowledge of the background developmental theory).

This is followed by *Creating Responsive Learning Environments to Develop Students' Reflective Capacity* from Patric Wallin, myself (Jonathan Reams), Sven Veine and Martha Kalvig Andersen. This article describes aspects of the theoretical foundation for and a description of some exploratory research on applying a computer aided developmental assessment (Lectica's CLAS) to creating a responsive learning environment. The theory behind this work focuses on how to support students in the move to self-authoring their learning processes. They explore how using formative assessments based on models of cognitive development can generate learning environments that can be responsive to students' natural learning and growth. The focus of application is on a large scale university course in Norway where students need to build reflective judgment skills and apply them to teamwork. While the research is in the early phases, it is an interesting application of developmental thinking to attempts to produce scalable classroom tools for supporting the development of the key skill of reflective judgment.

Rounding out our peer reviewed section is Zakary Stein's *Love in a Time Between Worlds: On the Metamodern "Return" to a Metaphysics of Eros*. This theme of deep explorations of an integral view finds its expression here in Stein's focus on a metaphysics of eros as the eternal struggle in this world between forces of love and death. To enable an adequate metaphysics in today's postmodern climate, Stein first lays a foundation for how we can practice metaphysics today, delving deeply into post Kantian thinking and taking up this thread after Darwin through Pierce into what he highlights as a "guerilla ontology." This is a highly educational journey that helps contextualize an array of key threads of thought at the heart of the second part of this article. There, Stein goes into how all of this applies to an understanding of eros as the heart of love and sex, reality and politics. I found it as a kind of meta-thread when Stein shows how errors in thought and ethics are traced back to the priorness of emotions and failures in relationships, linking back to Marman's understanding of relationships being at the heart of not only biology, but even quantum physics. The end of Stein's article focuses on how Gafni's *A Return to Eros* addresses these and other issues that help us get out of the postmodern swamp and back to a solid foundation in a reality where love can be prioritized and realized.

Our editorially reviewed section begins with Bonnitta Roy's presentation of her master thesis in consciousness, *Awakened Perception: Perception as Participation*. Regular readers of IR will have seen a number of articles from Roy over the years that show the breadth and depth of her thinking as well as its evolution. In this piece, we are treated to an inside look at the path of exploration she has recently engaged in. This covers research on perception itself, neurodynamics as the gates of perception, the role of the brain and senses in perception and the imagination, all leading to a conception of awakened perception, which is then examined in relation to Buddhist thought on the subject. As well, for those who are following and or applying her work on Open Participatory Organizations, this piece will provide insights into the foundations of the innovative applications she has been using to help people organize in ways that encourage natural organization around maximum participation.

I had the good fortune to be in London last May for the 2018 European Society for Research in Adult Development (ESRAD) conference. For me, and a number of others, one of the highlights was Thomas Jordan's hour long session where he presented the set of propositions laid out in *Late Stages of Adult Development: One Linear Sequence or Several Parallel Branches?* The quality and energy of the conversation that arose from considering these propositions made it clear that the questions Jordan raises are ripe for exploration among a growing community of researchers adequately prepared to begin addressing the questions Jordan lays out. In his article he lays out key concepts related to the different lines of research and theories he addresses and then lays out six propositions for us to consider, followed by five examples of profiles of people with different profiles combining various aspects of late stage development. The conclusion is an invitation to engage more robust sets of analytical constructs in our attempts to understand these phenomenon.

Susanne Cook-Greuter has graciously provided us with her keynote talk at the 2018 Integral European Conference, *The Construct-Aware Stage of Ego Development and its Relationship to the Fool Archetype*. In her warm and engaging style, she engages in Foo-ling as a means to illustrate the means by which construct awareness can be realized. She describes the role of language in shaping culture and consciousness, gives a brief overview of ego development theory and then examines the characteristics of fools and the fool archetype. This allows Cook-Greuter to make a list of shared characteristics which shows that wisdom and foolishness, leading to an admonition to not take ourselves too seriously and to laugh more!

For our next item, I have continued my interest in providing extended overviews of books that I believe to be of interest and relevance for our community of readers. In *The Nordic Secret: What can we Learn?* I present a chapter by chapter overview of the book *The Nordic Secret: A European Story of Beauty and Freedom*, which traces key influences on what the authors, Lene Andersen and Thomas Björkman consider as the foundation of Nordic success. Essentially, this involves an engaging narrative through the German Enlightenment and how the central ideas of the time articulate the perennial philosophy and closely match current notions of ego development. These ideas then shaped efforts at a people's education in Scandinavia and laid a foundation for a robust participatory democracy. How this could be adapted for today’s societal challenges is also addressed. The book is a wonderful application of integral thought to historical and current society.

Finally, Matthew Rich-Tolsma presents a review of Jennifer Gidley’s *Postformal Education: A Philosophy for Complex Futures*. He offers a penetrating examination of both the context and content of Gidley’s work, outlining the four core pedagogies; love, life, wisdom and voice. Rich-Tolsma captures the essence of Gidley’s work while also pointing to how choices made in the approach can also present limitations to the impact of the work.

With this, we hope that you enjoy the diverse feast laid out in this issue of *Integral Review*!

The Lenses of Perception Interpretation of Quantum Mechanics

Doug Marman[1]

Abstract: A new interpretation of quantum mechanics (QM) shows that all of the baffling behavior of fundamental particles that make QM so hard to comprehend are consistent with the behavior of biological lifeforms involved in receptive-responsive relationships with one another and their environment. This raises a radical possibility that fundamental particles possess a form of sentience and this sentience enables them to form relationships that create all of the tangible matter and energy and the spatiotemporal dimensions of our universe. This paper proposes a set of underlying principles to explain how this works at the quantum level. These principles are shown to be consistent with quantum formalism. Further, this paper shows that these principles offer an intuitive explanation for why the formalism of QM takes the form that it does.

Quantum formalism tells us that quantum states cannot be measured directly in their natural "coherent" form, and that quantum states must evolve gradually and linearly until a measurement occurs. Why? And why is all matter and energy quantized into packets that behave like particles when they are measured, but act more like waves when they are not being measured? And why do entangled particles act as if they "know" and "respond" to each other's state no matter how far apart they are?

This paper proposes that *if sentience is the cause* of this strange behavior, then the irrational nature of human relationships that we experience every day *can* offer insights that directly relate to the strange behavior of quanta. This opens the door to an intuitive understanding of QM.

This paper shows that there are three fundamental lenses of perception (sentient ways of sensing and responding) that appear to guide the behavior of all quanta and living organisms: first-person, second-person, and third-person perception. Quanta and life forms use these three lenses to form different types of relationships, and these relationships are what create the natural universe. These principles reveal an intangible aspect to sentient relationships, represented by quantum states that shape everything happening in the tangible, measurable world.

However, the main value of an interpretation of QM is its ability to offer potential solutions to existing problems in science. Two speculative proposals will be reviewed briefly. The first offers new insights into how the field of space may emerge at the quantum level. This has the potential to resolve the problems with developing a

quantum theory of gravity. However, the most startling prediction of the Lenses of Perception (LoP) Interpretation is that quantum behavior must be involved whenever living creatures engage in relationships with each other and their environment. This prediction is unavoidable if the interpretation is right. It also offers a simple way to test the theory. If this interpretation is sound, it has far-reaching implications for biology, psychology, and other social sciences because it shows that quantum effects play roles in all of those fields.

Introduction

Quantum mechanics has proven itself to be one of the most important scientific breakthroughs in history. The astounding accuracy of QM now displaces classical physics, especially when working on small scales near the sizes of atoms. However, the philosophical problem with QM is that it also displaces a number of important concepts of classical physics, such as the principle of cause-and-effect; the meaning of forces; the solidity of matter; and the ability to position ourselves as independent outside observers when running experiments.

The observer problem has serious ramifications: It means that there is no accurate third-person perspective for quantum interactions. This goes to the heart of what makes QM so baffling.

The impact of the observer cannot be avoided in quantum experiments because trying to measure or observe fundamental particles alters the outcome. This is not just due to the fact that shining a light on subatomic particles means hitting them with photons that carry a force. No, the problem goes much deeper. There is no way to gain direct information about fundamental particles without entering into a quantum state with those particles.

This limitation of observation is directly related to "the measurement problem" in QM, which will be discussed in more detail later. This is the biggest issue that interpretations of QM try to resolve.

There are more than a dozen interpretations that are consistent with the mathematical formalism of QM (Schlosshauer, Kofler, and Zeilinger, 2013). They each try to expand our understanding of the natural world and the meaning of QM. However, in many cases they contradict each other, which means that these interpretations cannot all be valid.

Two recent papers give a good example. Both offer excellent insights into QM, and both are fully consistent with QM formalism. Yet, they paint very different pictures of what the puzzle of QM is really about. The reason for this is that they each focus on different parts of the puzzle.

The first paper, "Relational Quantum Mechanics," by theoretical physicist Carlo Rovelli (2008) tries to get at the core of the difficult "sense of unease that quantum mechanics communicates" (p. 1). In his paper Rovelli offers two ideas: First, that there are no such things as observer-independent states of quantum systems, and there are equally no such things as observer-independent values of physical qualities (p. 1). In other words, in quantum mechanics there are only relational states and relational measured values. Second, he says that "quantum mechanics will cease to look puzzling only when we will be able to *derive* the formalism of the theory from a set of simple physical assertions ('postulates,' 'principles') about the world" (p. 2).

The second paper is "Taking Heisenberg's Potentia Seriously," by physicist/philosopher Ruth Kastner, biochemist Stuart Kauffman, and philosopher of science Michael Epperson (2017). This paper proposes that "quantum mechanics evinces a reality that entails both actualities…and potentia" (p. 8), where the later are invisible, intangible, quantum possibilities that exist outside of space-time dimensions and yet influence all tangible actualities within space-time. Both actualities and potentia are, therefore, "ontologically significant." This perspective "accounts naturally for the counter-intuitive features of quantum mechanics such as nonlocality, entanglement, and instantaneous collapse" (p. 15). Interestingly, this paper also makes a point to argue for using a “constructive theory” (p. 8) that offers a model for how quantum processes work, rather than a “principle theory,” as the best way to gain insights into physical processes underlying quantum phenomena.

Later I will return to these papers in more depth to show that they both offer valuable insights. But the point I want to illustrate here is that these papers present two very different pictures, and neither picture naturally leads to the conclusions of the other. How does the relational nature of quantum states and properties lead to the conclusion that actualities work differently from quantum potentia and both are real? Or how does the dual nature of physical reality lead to the conclusion that all quantum states and measured values are relational; none are observer-independent? At the same time, each paper argues for opposite approaches in how best to understand quantum phenomena.

More importantly, Rovelli’s paper still leaves us with the question of why all quantum systems exist only as observer-dependent states. This seems just as unsettling and hard to comprehend as the puzzle of quantum mechanics that it hopes to help us understand. And if we take Heisenberg’s potentia seriously, we are still left asking: What does it mean to say that quantum possibilities exist as a form of reality when those quantum possibilities are not actualities? In both cases, the baffling nature of quantum mechanics remains, as if to remind us that although we seem to be taking steps in the right direction, we are still no closer to making sense of it all.

In this paper, I hope to show that both a theory of principle and a constructive theory are needed to find an interpretation that is comprehensive enough to allow us to see how all these puzzle pieces fit together. Using both approaches can then show us why “Relational Quantum Mechanics” falls short of solving the measurement problem, while “Taking Heisenberg’s Potentia Seriously” does offer a working model that helps us understand the measurement problem, but does not go far enough to identify the underlying principles that explain why our physical world is composed of a duality of actualities and quantum possibilities in the first place.

If I was going to summarize the central issue that makes quantum mechanics so baffling, I would say that it begins with the scientific desire to establish quantum theory only on the tangible results of repeatable experiments and the attempt to reduce those results to a formalism that accurately predicts what will happen in the real world under any conditions.

There is nothing wrong with this desire except that it is limited solely to a third-person perspective, as if we are independent observers. Unfortunately, using this lens makes it impossible to see what is happening at the quantum level. We will never understand the full meaning of quantum interactions from an outsider’s perspective because, as Rovelli shows, there are no observer-independent quantum states or values. Only relational states and measurements appear to exist. This means we need a relational lens to understand what quantum behavior means. However, this still leaves us with questions: Why does the physical world behave this way? And what does it mean?

Albert Einstein, one of the founding fathers of quantum theory, could not bring himself to accept the whole picture of QM. He felt something important was missing. QM didn’t make sense as a complete theory. Rovelli (2017) tells the story:

> On the one hand, Einstein proposed Werner Heisenberg and Paul Dirac for the Nobel Prize, recognizing that they had understood something fundamental about the world. On the other, he took every opportunity to grumble that all this did not, however, make much sense.
>
> The young lions of the Copenhagen group [Heisenberg, Neils Bohr, and others] were dismayed: how could this come from *Einstein* himself? Their spiritual father, the man who had the courage to think the unthinkable, now pulled back and feared this new leap into the unknown – the very leap that he had himself triggered? How could it be the same Einstein who had taught us that time is not universal, and space bends; the same person now saying that the world could not be *this* strange? (pp. 137-138)
>
> [Einstein] refused to accept the relational aspect of the theory, the fact that things manifest themselves only through interactions… Ultimately, Einstein accepts that the theory represents a gigantic leap forward in our understanding of the world, and that it is coherent. But he remains convinced that things could not be as strange as this theory proposed – and that "behind" it there must be a further, more reasonable explanation. (p. 139)

This paper suggests that Einstein was right to reject the idea that things manifest *only* through interactions, and he was right to think that something more is going on behind those interactions that can offer an explanation that makes more sense. As will become clear, the missing element is an intangible aspect of reality called the "quantum state," that cannot be seen directly by third-person perception but plays a vital role in everything that happens in the tangible world. What we need is a way to understand this quantum state. What is it and what does it mean?

Although quantum states, as described by physicists, seem baffling and bizarre, because we cannot see them directly, they are, in fact, something that biologists, psychologists and social scientists should recognize as familiar, because they run into a similar situation when trying to study living creatures. They know that there is no way to see how organisms or human beings live in their natural state (when they are not being observed), because it is only possible to study how they behave when scientists observe them.

Or to put this another way: Organisms naturally respond to being measured because, whether we realize it or not, the act of measuring and observing creates a relationship with living things that alters how they behave. When marine biologists study the feeding and breeding behavior of fish, or zoologists study the social interactions of gorillas, they know that they are not just observing, they are also being observed. This suggests that if there is a possibility that quanta are sentient then a relational lens *is* needed to unravel the meaning of quantumness and where it comes from. It also suggests that there *is* something more going on with receptive-responsive relationships between quanta that *does* make sense of their behavior.

While this paper explores the possibility that quanta themselves might in some way be related to sentience, it does not start with this proposition. It begins in section 1 with a long list of similarities between the behavior of quanta and the behavior of living organisms. These behaviors represent the most puzzling aspects of QM. The list of remarkable similarities is so long and comprehensive that it begs the question: Do quantum entities possess some form of consciousness?

This leads to a quick, informal test of this interpretation in section 2, just to see if it holds any merit. If sentience is responsible for quantumness, then it leads to an inescapable prediction: We must see all of the seemingly inexplicable behaviors of QM at the level of sentient organisms as well. If this is true, it contradicts one of the most widely accepted tenets of QM theory: that some quantum behaviors are visible only on small scales. More importantly, if this conjecture is right, it sheds an important light on the meaning of quantum behavior, and it shows that quantum behavior must play a fundamental role in biology and all of the social sciences, especially psychology.

The fact that observers can no longer be ignored, that they are always involved in the measurement process, has led some physicists to propose that the consciousness of the observer might be the key to solving the measurement problem (von Neumann, 1955, & Wigner, 1961). However, those interpretations have fallen out of favor for good reasons, because recent experiments show that the measurement problem still exists even when test configurations are altered randomly and no person observes the results until long after the data are collected. This does not rule out the involvement of consciousness, but it does suggest that any influence on measurements by human observation does not resolve the underlying questions about the measurement process.

This raises one of the most significant criticisms that can be aimed at this current paper: whether it has the rigor necessary for a formal interpretation of QM. There is a good reason to raise this question because this paper is dealing with the notoriously difficult-to-define nature of consciousness.

This paper argues that complete analytical rigor is not necessary or even desirable when looking for a way to interpret and understand QM. Where rigor is needed is in testing theories. For this hypothesis to be testable, therefore, it must offer clear descriptions and models for what quantum states are and how they change. Therefore, this paper needs to explain how consciousness is involved in relationships between quanta in a way that is clear enough to be rigorously tested. This is dealt with in section 3.

After passing the informal test in section 2 – to assure that this approach is worth exploring – and finding a way to work with sentience in a scientific manner, in section 3, the paper presents the underlying principles that govern quanta in section 4. These principles also lead to a constructive model that is consistent with Heisenberg’s potentia. Section 5 then shows that these principles are consistent with the mathematical formalism of QM. Further, it shows, as Rovelli suggests, how quantum formalism can be derived from a set of underlying principles.

In section 6, the paper discusses implications, challenges, and opportunities for further research.

1. Similarities between Quanta and Living Organisms

Before looking at the similarities between quanta and living organisms, there are two lessons from classical physics that can help guide our way to a more comprehensive understanding of QM.

The lens of perception used by classical physicists, which is based on the third-person perspective, grew largely out of Isaac Newton’s approach to studying the force of gravity. He developed the mathematical tool of calculus to understand motion and changes in motion (acceleration). From this he drew startling conclusions about the laws of motion in general. For example, unless an external force acts on an object, the object will never change its speed or direction. And the acceleration of an object is determined by the force that is driving it.

However, a closer look at Newton’s calculus, as in Marman (2016) shows that analyzing generalized changes in motion produces a far more complex picture. The equation looks like this:

The distance an object moves over time = $V + ba_1{}^2 + ca_2{}^3 + da_3{}^4$... (p. 23)

The three dots at the end tell us that the formula is infinite. It never ends. Newton simplified the equation by using a powerful device: studying one force at a time. If we look at only one force acting on an object, then calculus reduces the above equation to this:

Force = (mass) x (acceleration)

That makes changes in motion manageable, and this is the basis of Newton’s second law of motion. But few physicists realize how much has been lost to achieve this simplicity: It only applies to cases where an external force acts on an object, and it only applies to forces that act independently. It does not include the possibility of multiple *internal* influences being involved in the dynamics. As a result, it no longer gives us a general description of changes in motion.

This turns out to be crucial when studying living creatures because biologists have clear evidence that even the simplest organisms initiate changes from within, as biologist Martin Heisenberg (2009), son of the physicist Werner Heisenberg, explains:

> The idea that animals act only in response to external stimuli has long been abandoned, and it is well established that they initiate behaviour on the basis of their internal states, as we do. (p. 164)
>
> Evidence of randomly generated action – action that is distinct from reaction because it does not depend upon external stimuli – can be found in unicellular organisms…. What this tells us is that behavioural output can be independent of sensory input.... The physiology of how this happens has been little investigated. But there is plenty of evidence that an animal's behaviour cannot be reduced to responses. For example, my lab has demonstrated that fruit flies, in situations they have never encountered, can modify their expectations about the consequences of their actions. They can solve problems that no individual fly in the evolutionary history of the species has solved before. Our experiments show that they actively initiate behaviour. (p. 165)

Newton’s approach cannot be used to explain the sentient behavior of living things because his second law only applies to singular external forces acting on objects. If we cannot use Newton’s second law, then we need a different lens to understand biological life because the principle of cause-and-effect and Newton’s laws do not apply to changes in motion originating from within.

It turns out that this same issue exists in QM as well. Physicists do not see external forces directing the behavior of individual quanta. Instead, what are interpreted as forces emerge from invisible quantum exchanges between particles. In other words, forces emerge from relationships. (More on this later). This is why QM sees the forces of classical physics more as outcomes than causes.

Here is a second interesting insight from classical physics that might help explain the seemingly bizarre world this paper is exploring. Physicists have struggled with trying to understand why human beings experience time flowing only in a forward direction (Penrose, 1989, p. 302). If we use the traditional third-person lens of classical physics, time looks as if it is spread out from past to future like a separate dimension. This third-person view of time shows no reason for time to flow in only one direction. In fact, it does not even suggest that time flows at all.

It is not just our experience of the forward flow of time that presents a problem for physics. Our first-person perceptions give us a clear experience of time that we call the moment "now." In fact, our experiences suggest that "now" is a continuously flowing passage between past and future. Hence, the *experience* of "now" appears to be the only moment of time that exists. The past, as well as future possibilities, do influence all sentient creatures, but organisms experience directly only what is happening now. Classical physics, on the other hand, has no way of determining any special meaning for "now" (Mermin, 1998); it is just a point on a line like any other point.

Our experiences also show that our perceptions of time can vary dramatically from one situation to another. For example, time may seem to speed by when we are having fun with friends, while it drags when waiting in line at a store. Because of these widely varying experiences of time, our perceptions are often considered subjective and then discounted. However, this misses the fact that these experiences with time are not happening solely within ourselves. They come from relationships with others in the world. Or, to make this point clearer, time appears to vary depending on our relationships. Experiences with relational time do not follow the tick of an externally imposed time-frame. They are context-dependent and personal.

This shows that although the third-person lens may be ideal for understanding mechanical cause-and-effect reactions, it does not show us everything that is happening. We face the exact same challenge with quantum behavior; we appear to be missing some vital aspect beneath the surface of tangible phenomena. And, as we will see later, what we are missing may have everything to do with the intangible dynamics of relationships between sentient agents.

Now, let's turn to the resemblances between quanta and organisms.

1.1 Indeterminacy

Quantum theory says that an individual particle's actual behavior is unpredictable. Equations can accurately determine the probabilities of where photons might hit a screen, for example, but there is no way of knowing where a single photon will actually land before it does.

This suggests that the landing spot is not determined by outside influences alone. External forces only shape the probabilities of what will happen, they do not determine individual outcomes. This is one of the strange realities of quantum mechanics. This was also one of Albert Einstein's biggest problems with QM. He felt that it was an indication that quantum theory is incomplete, leading to his famous comment, "God does not play with dice." In other words, he felt that there needed to be some kind of explanation for the indeterminate behavior of quanta.

Exactly where a photon lands can be compared to a swimmer in a sea of shifting currents reaching out to helping hands on a rocky shore.[2] Which hand will the swimmer grab? Indeterminacy shows us that photons and other particles are not actually "forced" into position by forces. They are only influenced. If this is true – and physicists have proven this over and over again – then what determines the end result?[3] This is one of the unsolved mysteries of QM.

Many interpretations of QM have proposed possible answers. For example, the von Neumann-Wigner Interpretation (n.d.) suggests that the quantum wave-function, which describes how quantum possibilities evolve, "collapses" down to one actual outcome through the consciousness of the observer. But, even if this were true, it offers no insight into how or why one possibility is selected over another. Therefore, it does not solve this problem.

The Many-Worlds Interpretation (n.d.) tries to get around this issue by suggesting that all possible outcomes take place in different universes. Unfortunately, these parallel universes are beyond our reach, so we have no way to test this. But even if this interpretation were right, it still wouldn't explain why the photon in our universe arrives where it does. It simply says that we are living in a world where it lands on that spot. This does not help us understand what is happening or why.

The Copenhagen Interpretation does not recognize the "wave collapse" as real because the wave equation cannot show how it happens. This is one of the reasons why Bohr said that the quantum realm is impossible to understand (Kastner, 2016, p. 1 and p. 14).

The "Taking Heisenberg's Potentia Seriously" paper offers a model that does a good job showing that the wave collapse is real and how it works (pp. 6-12). However, it still cannot explain why, only that specific one possibility out of many becomes an actuality. (More on this later).

The "Relational Quantum Mechanics" paper suggests that, somehow, the actualized state emerges from relationships with the environment through a process called "decoherence," but even if this were true (and, as we will see later, there are good reasons to suggest that it is not), this approach offers no good explanation for why the quantum state instantaneously and irreversibly "collapses" to one actuality and not another.

Yet, when we look at the behavior of living things, we see this exact same trait of indeterminacy. Why? Because they can initiate behavior. Yes, they are clearly influenced by external forces and constraints, but they also possess a degree of internal agency. They do not function like clockwork machines that follow programed trajectories determined solely by outside forces. They respond to the environment based on their relationships with their habitat.

When studying the behavior of single-celled bacteria, biologists can predict how a cell will act *on average*, but they have no way of knowing what one will do in any single case. This is the nature of living things.

---

[2] My thanks to Alan Rayner for this graphic metaphor.
[3] For an overview of the science behind this, see my discussion in Marman, 2016, pp. 239-247.

Animals behave as if they possess “free will.” The problem is that outside observation cannot determine where this autonomous ability comes from. And the term “will” is equally problematic, since it suggests causative action that is also impossible to observe by outsiders. But some form of internal agency is evident in all living creatures. Thus, the homily of biologists that dead fish are the only fish that *only* swim with the current.

1.2 The Quantum Nature of Energy and Matter

Here is another fundamental resemblance between quanta and living things: They both behave as individual agencies.

A central principle in QM theory is that energy and matter must always be quantized. Individual particles (or wave-fronts, if you prefer that model) are needed to carry energy and mass. These packets cannot be reduced to fractions of a packet: There is no such thing as half a photon.

Why? No interpretations even try to explain this. It is simply accepted as a necessary postulate of quantum mechanics. However, cells and living organisms also act as individuals. In fact, their individual nature becomes clear by the way they carry energy and mass. In other words, it comes down, once again, to their intrinsic agency.

You can, of course, cut creatures in half, but if you do they will either die or regenerate from one or both segments into individual functioning bodies once again. On the other hand, if you kill them, they stop acting as individuals. Their bodies settle into equilibrium with the environment.

This shows clearly where the nature of their individuality and identity come from: their internal agency. It does not come from their energy or mass, but what they do with energy and mass.

1.3 Individuality and Internal Agency Does Not Mean Independence

This leads to a surprising resemblance: Fundamental particles cannot exist independently of their environment any more than living creatures can.

We know that all animals, plants, and organisms need air, food, and water to thrive. If you prevent them from making exchanges with their habitat, they will die. This dependence on the environment is well accepted by biologists. But it is startling to find similar behavior in quanta.

According to quantum theory, electrons, by themselves, are dimensionless points. When they are measured, however, electrons act as if they contain space and possess a body (Cartlidge, 2011).

Physicists have learned that, in order to get accurate results that describe the observed behavior of electrons using quantum field equations, each electron must be treated as if it is surrounded by a cloud of invisible “virtual” particles. This mathematical adjustment is called “renormalization.” Without this cloud, the electron would act as if it contains no physical space. In other words, virtual particles appear to give electrons their bodies. The same is true for all matter particles, including all types of neutrinos, muons, and quarks.

However, the dependence of particles on their environment goes further. Every matter-type particle must also belong to a particle field. For example, electrons are members of a universal collective called the "electron particle field." Particle fields give particles their properties of mass, charge, and spin – their uniform, if you will. This is why every electron has a single negative charge, along with the exact same spin and mass. This means that if you take an electron from its particle field it will "die" and no longer exist as an electron.

This description might seem like a bit of a stretch until we see how the "weak nuclear force" affects electrons: It causes them to decay – which means they cease being electrons. They stop carrying energy and mass the way that electrons do. And after an electron decays from the weak force, a new particle is born that suddenly starts wearing the uniform of neutrinos instead.

However, this neutrino is not an unrelated new particle because there is a clear continuation of agency from the electron to the neutrino. In other words, it appears as if the electron dies and is then reborn as a neutrino.

The point of this is that a particle must belong to a particle field. In fact, many physicists say that it is impossible to separate fields from particles. Rovelli (2017) put it this way: "Fields and particles are the same thing" (p. 126). In other words, particles cannot live without fields. The lives of organisms similarly depend on their relationships with members of their species and their habitat.

1.4 Entanglement

One of the clearest resemblances between quanta and organisms comes from the baffling nature of quantum entanglement. Experiments prove that this is an outwardly strange but intrinsic property of reality. When particles become entangled, they share a quantum state that aligns them.[4] They can stay aligned to the same shared state even after flying miles away from each other.

For example, take two entangled electrons that have opposed reciprocal spins. Their spins remain reciprocal indefinitely. Even if the spin of one is altered by an outside influence, such as a measurement of their spin, the other will reciprocate. Even stranger, it does not matter how far apart the two electrons are in terms of distance.

How do they know how to stay aligned when they are miles apart? More importantly, why and how do particles become entangled in the first place?

Neils Bohr's advice was to stop asking these questions because it is impossible to see what is happening at the quantum level; this is just the way particles behave. Bohr said: "There is no quantum world. There is only an abstract physical description. It is wrong to think that the task of physics is to find out how nature is" (as cited in Petersen, 1963, p. 12).

As other physicists have pointed out, this had a "chilling effect" (Kastner, 2013, p. 8) on the pursuit of comprehending quantum behavior. Before Bohr's comments, it was the job of physicists to search for a deeper understanding. Afterwards, it was generally considered to be a waste of time (Mermin, 1990, p. 198).

---

[4] For an overview of the research on this, see Quantum Entanglement (n.d.).

However, if we use relational lenses, rather than taking a third-person perspective, we see that quantum entanglement looks quite similar to what we experience in human relationships. Adesso (2007) and many other physicists have used the same comparison. For example, the physicist, John Bell (as cited in Bernstein, 2009) used the following way of explaining entanglement to others:

> identical twins who had been separated at birth. Bell discovered that there were a number of pairs that had been reunited later in life to find that they had a remarkable number of things in common, including smoking the same brand of cigarette. (p. 172)

This does not mean that these physicists are suggesting that human relationships and quantum entanglement are the same. Not at all. They are simply offering human relationships as examples because it gives people a reasonable way of relating to what entanglement entails.

For example, if we look at our own friendships, we feel an affinity and sense of rapport that aligns us with our friends. We complete each other’s sentences. We laugh at the same jokes. We feel their pain when they are suffering, and their thrills of success, as if they are our own.

We feel the influence of this intangible alignment with others no matter how far away we might be from them. We think of them during the day because this invisible affinity seems to tug at us inwardly. We feel the possibilities of our relationships as if we share a kind of private emotional space with others, even when we cannot talk with them or send messages.

If we put on our third-person lenses and look at entangled electrons, if we position ourselves as outside observers, the thought that they could be emotionally involved seems preposterous. They are just electrons, tiny bits of matter. How could they feel emotions?

That is a perfectly understandable viewpoint. But, if third-person perspectives are the final word, we will not even try to explore this similarity. We will rule it out because it makes no sense to us.

This is how lenses of perception can blind us. They can prevent us from learning and seeing new possibilities simply because we have not yet learned how they make sense through another lens. As a result, it is easy to unconsciously reject perspectives that seem alien to our way of seeing.

However, the unexpected nature of reality keeps forcing scientists to look at the world in new ways. This is why we need to keep trying on new lenses, to see where they take us, no matter how uncomfortable they make us feel. This means crossing through a zone of confusion that can be unsettling before it starts to make sense. We should not let this hold us back if we really want to understand. This, in many ways, describes the present challenge we face with quantum mechanics.

What if entanglement *is* the result of relationships with some kind of inner dynamics similar to emotions? Can this help explain the mysteries of quantum mechanics? Honestly, the only reason to ask these questions is because there is such a long list of resemblances and similarities, all pointing to the same possibility.

1.5 Attraction and Repulsion

Here's another interesting resemblance: At the quantum level, electrons are not repelled by all other electrons, and they are not always attracted to every proton (Kastner, 2015, pp. 84-87).

Yes, we know that like charges repel and opposite charges attract, but this does not always happen between individual particles.

It is true that if you have two foam balls charged with billions of added electrons, they will *always* repel each other. But on the quantum level it is hit or miss. This sounds a lot like the emotional nature of relationships; they are unpredictable. We never know for sure who is going to hit it off.

We all know at least two friends who are not attracted to each other, even though we like them both. Yes, we see a general sense of attraction between men and women, but this certainly isn't true in all cases. The experience of emotional attraction between human beings is actually rare, which is what makes it special.

As I will show later, physicists have determined that attraction and repulsion between charged particles is also rare and that these responses are triggered by invisible quantum exchanges between them. This is mathematically described as virtual particles passing back and forth between charged particles. Virtual particles are intangible – there is no way to detect them directly. The process of attraction and repulsion can also be described mathematically as invisible wave functions that either add together or cancel each other out.

But why does one pair of particles hit it off when another pair does not? No other interpretation of QM offers an explanation. The third-person perspective has not been able to explain this mystery. In fact, it suggests that there is no way of knowing. But we know how it feels to be attracted to another person. It is often unexpected. If the other person confirms that they feel the same way toward us, then the experience of "chemistry" between us is reinforced and grows stronger. With validation, a relationship feels substantial and real.

So, this behavior of charged particles makes some sense if we compare it to the receptive-responsive exchange that we see in relationships between life forms. This, of course, still leaves the question about how this works. (A model that explains this will be explored in detail later).

1.6 Wave-particle Duality

Particles are notorious for displaying two different types of behavior: They show both particle-like and wave-like properties (Penrose, 2016, pp. 133-138). For example, photons look like particles when they light up one spot on a screen. They look more like waves when they create interference patterns. (More on this later).

We see a similar dual behavior with organisms. Their particle-like nature stands out when they act as individuals. Their wave-like nature, on the other hand, shows up when they are involved in the back-and-forth exchanges of relationships. This is especially noticeable when they are involved in collective group relationships.

Look at the shape of a rose: Its beauty arises from the delicate folds and ripples of its petals formed by countless living cells working in concert. All life forms are involved in continual exchanges with the world – the rhythmic breathing in and out, beating of hearts, and the inflow and outflow of material exchanges with their habitat. Wave-like behavior is easy to see.

All creatures are affected by the groups they are involved in. This raises the question: Does the wave nature of quantum states derive from dynamic relationships?

1.7 The Uncertainty Principle

Werner Heisenberg (1927) published his famous paper on the Uncertainty Principle which says that the more accurately we determine the location of a particle, the less accurately we can determine where it is going, and the more accurately we determine where a particle is going, the less we can know about its location.

As Bowman (2008) says, for many years this unexpected discovery was so at odds with classical physics that it was seen as describing the defining trait of quantum mechanics itself (p. 82).

A complete explanation for why this inherent uncertainty exists is not known. However, physicists know that there is a relationship between measuring the position of a particle and measuring where that particle is going. As a result, if you measure where a particle is located first, and then measure where it is going, you will get a different answer than if you measure where it is going first and then measure its position. This is equivalent to saying, in mathematical terms, that “*A*” times “*B*” is *not* equal to “*B*” times “*A*”.

To get a better sense of the impact of the uncertainty principle, let’s look at two examples. First, if you create a very narrow slit for photons to pass through, then when the photon is in the slit, the location of that photon is well defined. This means that we should see an increase in the uncertainty of where that photon is going. This is exactly what happens: photons head off in all sorts of directions when exiting the slit. This is called “diffraction.” Feynman (1985) describes the result this way: “So when you try to squeeze light too much to make sure it’s going in only a straight line, it refuses to cooperate and begins to spread out” (p. 55).

Here is a second example: Electrons do not orbit the nucleus of an atom. Their location is more like a cloud. The reason for this is that the electrons are in stable, clearly defined momentum states, called electron shells. For example, when an electron is in the lowest energy state in a hydrogen atom, the electron has no angular momentum at all. If the momentum is in a stable and fixed state like this, then the electron’s *position* must be highly uncertain. This is why physicists describe the possible locations for an electron to be like a cloud, because they have no clear position. It turns out that this is what creates the hard shell around atoms that gives matter its appearance of solidity:

> Now, suppose you tried to squeeze that electron cloud down to a smaller cloud. This would decrease the uncertainty of its position by confining it to a smaller region. The HUP [Heisenberg Uncertainty Principle] then dictates that its momentum – in this case, momentum straight inward or outward from the nucleus – would become more uncertain. With increasing uncertainty in momentum comes a greater likelihood of a larger momentum, which corresponds to more energy of motion. More energy of motion means

> a greater resistive force pushing outward. Therefore, the tighter a space you try to cram the cloud into, the more energetically it will resist. (Kastner, 2015, pp. 81-82)

In both of these examples, the more we try to nail down where quanta are or where they are going, the more they push back. We see this same trait when trying to control animals. Living organisms resist being forced to obey completely because it denies their ability to move and act. They need freedom to find food and form relationships – in order to live. The only way to completely stop a creature from moving is to kill it. Thus, the natural ecology on our planet can never be fully forced or controlled because life has a way of its own that springs from sentience.

The only way to stop a particle from moving is to annihilate it, because if a particle ever did become perfectly still, it would have a fixed position and no momentum. The uncertainty principle forbids this. Therefore, every particle must always be in motion (Smolin, 2017, p. 83).

Even Werner Heisenberg's son, biologist Martin Heisenberg, wrote about the relationship between the uncertainty principle and the "free will" behavior of biological organisms (Heisenberg, M., 2009). A number of physicists have also seen this relationship between the uncertainty principle and free will. For example, experimental particle physicist Bruce A. Schumm (2004) wrote this:

> The uncertainty principle is one of the striking revelations of quantum mechanics, and it pervades the theory as a fundamental tenet that cannot be violated.... More interestingly, it is a revelation that seems to address questions of deep philosophical import. With the advent of the uncertainty principle, determinism, the notion that the laws of nature set forth an inextricable course of events from which no deviation is possible, becomes indefensible. According to the uncertainty principle, the exact course of events is fundamentally unknowable. There is always some uncertainty in the physical properties of any given object; not even nature herself knows how this uncertainty will resolve itself.... It's not just a matter of building a better instrument for determining these properties. The exact value is simply unknowable, even in principle. Many have gone on to conjecture that Heisenberg's uncertainty principle is the very source of human free will, but this remains to be demonstrated. (p. 42)

It is a fundamental trait of sentient agents to resist attempts to completely limit and control them. Dead bodies, on the other hand, do not push back. They reach equilibrium with the environment and stop opposing external forces. If this is right, then perhaps Heisenberg's uncertainty principle is *not* the source of free will. Perhaps the opposite is true: The need of quanta to act as sentient agents is the source of the uncertainty principle. (A model for how this works will be offered later).

1.8 Exchanging Energy

Here's another similarity: Kastner (2013) shows that real particles continually circulate and exchange energy. If they ever stop circulating and exchanging energy, there is no way of knowing if they exist in the space-time dimensions of our universe because they can no longer be detected. In other words, particles only become tangible through transactions of energy (p. 16).

Later, we will see that this circulating and exchanging of energy comes down to emission and absorption.

We see similar behavior with organisms: They can only live in this world if they continue gathering and expending energy. This means consuming (absorbing) food and eliminating (emitting) waste. In other words, life forms must engage in continuing work with the world to live here.

1.9 The List of Similarities

To this list we can add a ninth item, the similarity noted in the introduction: We cannot directly see how quanta behave in their natural state. We can only observe how they act when they are being observed. Trying to study living creatures runs into the same difficulty. It is as if a wall exists that obscures our ability to see what makes organisms alive. Taking creatures apart to study their organs gives us a clearer idea of their anatomy, but it can also bring an end to their life. In the same way, as soon as we try to study a quantum state by measuring it, it temporarily loses its quantumness. (More on this in the next section).

And we can add tenth and eleventh items to this list: quantum superpositions and the wave-function collapse, both to be discussed in the next section.

Clearly, some of these resemblances are more compelling than others. But, taken overall, they raise the question of why so many similarities exist. At a minimum, we should be asking: Is there something to be learned from this?

To explore these questions, the Lenses of Perception (LoP) Interpretation proposes that these are more than superficial resemblances: They imply that quantum particles have some intrinsic element of sentient awareness. Can this explain why quanta become entangled and form relationships with some but not others?

This possibility offers an intriguing perspective on many of the biggest mysteries of quantum mechanics. And sometimes just looking at problems in new ways can lead to new solutions. It may seem like an outlandish hypothesis, but that should not dissuade us. As Neil’s Bohr said, “We are all agreed that your theory is crazy. The question is whether it is crazy enough to have a chance of being correct” (Bohr, n.d.).

Fortunately, the LoP Interpretation offers more than a new perspective, it also gives us a clear way to test whether it is wrong.

2. The Inescapable Predication of the LoP Interpretation

The LoP theory differentiates itself from every other interpretation by predicting that we should see quantum behavior wherever living organisms form relationships. This is a necessary conclusion if the LoP Interpretation is right. It cannot be avoided.

If quantumness is caused by sentience, then we should not just see these seemingly irrational behaviors at the microscopic level. We should find the same exact patterns of entanglement, superpositions, uncertainty, the quantization of energy and matter, and the wave-function collapse, at every level where life forms relate to each other.

Quantum theory states that quantum effects disappear as you move from the microscopic level to the world of big things. If this is true, then the LoP Interpretation can be proved wrong by showing one principle of quantum behavior that is not at work at the level of organisms and human beings. Even one example of a true quantum effect is enough to disprove the LoP theory.

That should be easy, but it isn't. I have not been able to find a single case. All of the behaviors that we observe with fundamental particles that give us the "sense of unease that quantum mechanics communicates," as Rovelli put it earlier, can be seen in our lives as human beings and in the behavior of all organisms, even single-celled amoebas.

We have just reviewed the similarity between entanglement and human relationships. We know that both particles and organisms are carriers of energy and matter. Therefore, they both act as if they are individuals, and this means that the energy and mass of life forms is always quantized, the same as with quanta. In other words, there is no such thing as a living entity that is half alive. Biologist Alan Rayner and I wrote a paper on this exact subject (Marman & Rayner, 2016).

We also saw above how the indeterminate and unpredictable behavior of quanta is similar to the willful behavior of living creatures, and how particles and organisms display both a particle-like and wave-like nature.

This leaves us with two quintessential quantum principles: Superpositions and the wave-function collapse are both considered unique to QM. Both of these functions clearly occur at the quantum level, and there is nothing in quantum theory to suggest that we should see either of these at the level of human beings or single-celled organisms. This is especially true for superpositions because they quickly disappear when we move from the subatomic realm to the macroscopic world.

Therefore, it should be startling and unexpected to find these two principles at work in the lives of human beings and other creatures. But, if they do not play crucial roles in relationships between all life forms, the LoP Interpretation fails.

2.1 The Wave-Function Collapse

Of these two, the wave-function collapse is easiest to show because physicists have already written about this happening at the level of human beings. The reason human observation was proposed to be the cause of the wave-function collapse, as mentioned in the introduction, was because, according to quantum theory, the wave-function evolves in a linear, continuous manner, which means that there should be no way for it to change instantaneously. However, when a measurement is made, the quantum state makes a sudden, non-linear collapse to a single actual result.

The physicist, John von Neumann, explained this in 1932, when he published the first fully rigorous formal analysis of QM.[5] What he showed was that the wave collapse appeared to be completely different from the natural, gradual evolution of pure quantum states.

Up until then, the most popular explanation, based on the Copenhagen Interpretation, suggested that the collapse occurs when a quantum state "mixes" with the measurement equipment that is in a classical state. However, von Neumann showed that the equipment needs to be treated as a quantum system as well. This means that any equipment involved in a measurement becomes entangled with the quantum state being tested, according to the formalism. As a result, the equipment is no longer independent; it is now in a shared quantum state. If this is true, then this shared state should continue to evolve gradually and linearly.

---

[5] It was first published in German, then translated into English in 1955 (von Neumann, 1955).

Then when does the wave collapse occur? He looked at the overall process and could only see one place where something distinct and sudden happens: when the observer of the test recognizes the results. For the observer, this recognition creates an instantaneous shift in information. In that moment, the results become the knowledge of the observer (von Neumann, 1955, pp. 418-421).

As a result, the quantum leap that takes place with a wave collapse, according to the Copenhagen interpretation, does not represent an actual physical process, but merely a sudden change in the physicist’s knowledge (Penrose, 2016, p. 144).

We have to remember that QM experiments in the early twentieth century were not nearly as advanced as today. When they ran the famous experiment where photons are fired one at a time through two slits, they were surprised to see an interference pattern build up over time from where the photons hit the screen. How do single photons going through these slits create this wave-like interference pattern? Did each photon go through both slits at the same time, like a wave?

To answer this question, they set up detectors near the slits, to see if any photon went through both slits. When they ran the test this way, every photon was detected passing through only one of the two slits, not both. At the same time, however, the interference pattern suddenly disappeared. Somehow having detectors near the slits stopped the wave-like behavior of the photons.

They ran the experiment again, leaving the detectors in place next to the slits, except they turned the detectors off. The interference pattern returned. Photons regained their wave-like properties.

This is why physicists began to ask if the act of observation could be causing the photons to lose their wave-like “coherent” quantum state. But in the last thirty years, experiments have become far more sophisticated. There is now strong evidence that “decoherence,” which causes the interference pattern to fade, is gradual and is not the result of measurements.

In fact, decoherence theory says that decoherence happens when particles become entangled with their environment. The more a particle becomes entangled with other particles in the environment, the more information about the particle becomes known by the environment. This information causes the loss of interference patterns because a particle can retain its coherent quantum state only when it is not being observed by other particles, according to decoherence theory.

This tells us that decoherence is the result of the linear evolution of quantum states. And this suggests that decoherence actually has nothing to do with the collapse of the wave function.

This development has caused a great deal of confusion. Many physicists originally felt that for all practical purposes the measurement problem was solved and no collapse is needed. The founders of the science of decoherence stepped forward to make it clear that this is not true (Joos, E., *et al.*, 2003. pp. 4-5 and p. 357).

Decoherence only explains the interference pattern, not why a photon hits one point on the screen and not others. And decoherence cannot explain why each photon chooses one slit and not the other. These are not gradual changes. Photons do not gradually begin moving through one slit. They do not gradually select one spot on the screen over others. These are discontinuous selections that result in singular actual results.

The LoP Interpretation can add more clarity to what all this means, and we will get into more detail about decoherence later. But for now, let’s look at how the wave-function collapse of QM is similar to what happens at the level of human beings.

At the quantum level, a collapse is not deterministically caused by outside forces. This is why quantum equations can only predict probabilities, not individual outcomes. We see something surprisingly similar in relationships between people. No one, not even the people involved, can know for sure which relationships will develop into lasting friendships or marriages.

Outside influences, such as friends, family, and society in general, do indeed have an effect on the outcome, but the fate of a relationship is largely determined by what develops between the people involved. Still, when it comes to a couple that decides to move in together or get married, a shared decision must be made. In that instant, the gradual evolution of their friendship makes a sudden shift. In other words, this is an instantaneous leap that is irreversible. Even if the couple later decides to go their separate ways, there is no going back to the relationship they had before they decided to live together.

This is why the photon landing on a screen can be compared to a swimmer in a turbulent sea, where the hands of friends are reaching out from the rocky shore. Which hand will the swimmer (the photon) grasp? It all comes down to choosing one relationship over another, in a moment when the sea is rising and falling.

This example suggests that the wave function collapses when a single possibility emerges, out of all the possibilities, as the one worth acting on in that moment. One relationship stands out. The hand of that friend becomes the one the swimmer grasps. At the human level, it is easy to see, in a similar way, how intangible emotions and feelings become triggers for tangible choices.

This description is virtually identical to what physicists call “symmetry breaking,” which describes a sudden shift that happens within a field (Kastner, 2016, p. 16). Symmetry is a shared common property across a field, such as the relationship between gaseous water molecules in the air. They all keep about the same amount of distance from each other. However, if the air temperature drops, some of those water molecules start creating stronger bonds with each other as they come closer together. Which molecules make this change first? Once again, it comes down to choosing the relationships that align the closest. As soon as some water molecules start joining, the field of water vapor makes a phase change and water droplets start falling from the air as rain. Crystals, such as salt, emerge out of a solution of brine in the same way. When symmetry in a field breaks, it happens spontaneously within the field. The “Taking Heisenberg’s Potentia Seriously” paper says that a wave collapse occurs in the same way as quantum symmetry breaking; they both describe the same process (Kastner, Kauffman, & Epperson, 2017, p. 6).

Here is how physicist Lee Smolin (2007) describes symmetry breaking:

> Physicists … say that the symmetry between us at birth is broken by the situations we encounter and the choices we make. In some cases, it would be hard to predict the way the symmetry will be broken. We know that it must break, but looking at a nursery full of infants we are hard-pressed to predict how. In cases like this, physicists say that the symmetry is *spontaneously broken*. By this we mean that it is necessary that the symmetry break, but exactly how it breaks is highly contingent. This spontaneous symmetry breaking is the second great principle that underlies the standard model of particle physics.
>
> Here is another example from human life. As a faculty member, I've sometimes had occasion to go to receptions for new undergraduates. Watching them meet one another, it has occurred to me that over the next year some will become friends, others lovers, a few will even marry. At this first moment, when they encounter one another as strangers, there is a lot of symmetry in the room; many possible couples and bonds of friendship could be forged in this group. But of necessity the symmetry must be broken as the actual human relationships develop out of a much larger space of possible relationships. This, too, is an example of spontaneous symmetry breaking. (pp. 59-60)

Smolin's examples illustrate that symmetry breaking and the wave collapse, at the level of fields and quanta, are clearly similar to events that happen at the level of human relationships. Partnerships and marriages form, creating a new form of order in what was once a uniformly symmetric field. Water drops and crystals emerge as new visible forms in the same way. In other words, we see what appear to be new visible forms emerging from the invisible relationships between them. Something tangible emerges from the intangible inner dynamics of relationships between sentient agents. Later we will see how this works in detail.

For now, this passes the goal of this first informal test to see if wave-function collapses might also occur with living creatures. This test, of course, is far from convincing. But, for a first step this shows that, as radical as the suggestion is that quanta behave as if they possess sentience of some kind, there is no immediate reason to reject the possibility. Now, let's explore this in more depth.

2.1.1 Wigner's Friend and Third-Person Observers

Before we move on to the far more interesting case of superpositions, which will also be more controversial, I would like to take a moment to point out something that is becoming clearer from these comparisons between the behavior of particles and the behavior of organisms. This goes directly to the question of whether it is worth the time to pursue this line of inquiry.

When physicists use the term "wave collapse," or the term "spontaneous symmetry breaking," there is a great deal of vagueness about what these terms actually mean. How and why these events take place is hard to nail down.

Smolin says above that symmetry breaking is “highly contingent.” But, even if we can analyze all of the factors influencing an outcome, that will not tell us enough to determine exactly how and when the symmetry will break. The reason for this lack of clarity, I believe, comes from the fact that we are talking about processes that display a form of internal agency, but we are trying to look at this as outside observers by focusing entirely on the tangible results of experiments, while ignoring the intangible aspects of relationships.

However, when we talk about human relationships and how two people make a decision to live together or get married, we can relate to what this change means because we know what it feels like to be on the inside of relationships. As a result, a decision that couples choose together makes far more sense to us than changes that spontaneously emerge between quanta. Thus, it is easier to understand why relationships suddenly leap to a new phase between people.

This raises the key question of this paper: Can the insights we learn from human relationships, that we gain through experiences, help us understand the behavior of quanta? I believe the answer is yes, and it can lead to new insights that are testable.

For example, the physicist, Eugene Wigner, wrote a controversial paper (1961) that gained a lot of attention, especially outside of physics. In this paper, quoted below, he starts by summarizing von Neumann’s discussions about the way that human consciousness seems to be involved in the measurement process:

> When the province of physical theory was extended to encompass microscopic phenomena, through the creation of quantum mechanics, the concept of consciousness came to the fore again: it was not possible to formulate the laws of quantum mechanics in a fully consistent way without reference to the consciousness. All that quantum mechanics purports to provide are probability connections between subsequent impressions (also called "apperceptions") of the consciousness, and even though the dividing line between the observer, whose consciousness is being affected, and the observed physical object can be shifted towards the one or the other to a considerable degree, it cannot be eliminated. (p. 172)
>
> The important point is that the impression which one gains at an interaction may, and in general does, modify the probabilities with which one gains the various possible impressions at later interactions. In other words, the impression which one gains at an interaction, called also the result of an observation, modifies the wave function of the system. The modified wave function is, furthermore, in general unpredictable before the impression gained at the interaction has entered our consciousness: it is the entering of an impression into our consciousness which alters the wave function because it modifies our appraisal of the probabilities for different impressions which we expect to receive in the future. It is at this point that the consciousness enters the theory unavoidably and unalterably. If one speaks in terms of the wave function, its changes are coupled with the entering of impressions into our consciousness. If one formulates the laws of quantum mechanics in terms of probabilities of impressions, these are *ipso facto* the primary concepts with which one deals. (pp. 175-176)

Most physicists have good reasons for disagreeing with the way that von Neumann and Wigner describe the role of consciousness in QM, as we will see soon. Even Wigner himself abandoned this way of thinking when the science of decoherence was introduced, because it was entanglement with the environment, not human observers, that cause the interference pattern to disappear.

The mistake that Wigner and von Neumann make is that they confuse the wave collapse that happens at the human level (when the results become clear to the observer running the experiment) with the wave collapse happening at the level of quanta. Wave collapses, according to the LoP Interpretation, do indeed happen at both levels, but the levels should not be confused. Seeing quantumness as the result of sentience can help clear up this significant point of confusion.

However, what is important in Wigner's (1961) article that I want to look at now is that he took this discussion further and asked what happens in the case where he himself is not directly involved in a measurement experiment, but he has a close friend who is. This is famously called the problem of "Wigner's Friend," which is almost as famous as "Schrödinger's Cat." Wigner then analyzes the situation using the quantum formalism established by von Neumann:

> It is natural to inquire about the situation if one does not make the observation oneself but lets someone else carry it out. What is the wave function if my friend looked at the place where the flash might show at time *t*? The answer is that the information available about the *object* cannot be described by a wave function. One could attribute a wave function to the joint system: friend plus object, and this joint system would have a wave function also after the interaction, that is, after my friend has looked. (p. 176)

The reason that Wigner says the information available about the object cannot be described by a wave function is because he is relying on his friend for information about what happened. Wigner has no information of his own about the object except what his friend tells him. And what his friend tells him about the object is colored by his friend's entanglement with the object. We see the same thing when we listen to a friend tell us about someone they met – we know that their description of the person they met is going to be colored by their personal experiences with that person. (More about this later). Now back to the rest of Wigner's comment.

> I can then enter into interaction with this joint system by asking my friend whether he saw a flash. If his answer gives me the impression that he did, the joint wave function of friend + object will change into one in which they have separate wave functions (the total wave function is a product) and the wave function of the object is ψ_1. If he says no, the wave function of the object is ψ_2, i.e., the object behaves from then on as if I had observed it and had seen no flash. However, even in this case, in which the observation was carried out by someone else, the typical change in the wave function occurred only when some information (the *yes* or *no* of my friend) entered *my* consciousness. It follows that the quantum description of objects is influenced by impressions entering my consciousness. (p. 176)

If this is confusing to read, it is largely because Wigner is using the formalized approach for analyzing quantum interactions. The main reason this approach seems confusing is because it spends only a little time talking about the test itself and spends almost the whole paragraph talking about how to think about the information that we learned about the test and how we got that information. Wigner is saying above that if his friend reports that he saw a flash, then, the moment Wigner hears this, the state of two possible outcomes collapses down to one, for him. If his friend saw no flash, then the possibilities collapse down to the other option.

This formalism is necessary because we cannot see directly what is happening with unobserved quantum states, the same way Wigner could not see the test directly. All the information we gain comes from mixed states, and this means that we need to always remember that our information is colored by the observers who give us that information. We will get into more about this later.

For now, I want to focus on how vague the role is that consciousness plays in this description. It is easy to see why most physicists want to leave consciousness out of the discussion. Is Wigner suggesting that his hearing about the test from his friend played a role in the flash of light?

We can now add some clarity to this discussion by using the similarities between quanta and organisms that we looked at above. For example, later in his paper, Wigner (1961) says that if his friend is someone he knows, and his friend tells him that he saw the results of an experiment, then it would be "unnatural" to reject what his friend says. Few "people, in their hearts, will go along with" taking such a radical position (pp. 180-181).

Trusting his friend, therefore, allows him to accept information about the experiment without being directly involved. Wigner suggests that accepting information from his friend causes a sudden shift in what he knows about the test and this describes a wave-function collapse.

I think Wigner is making a good point, *if* we are talking about what is happening at the human level. There *is* a sudden shift in his perception of the test results when he accepts what his friend tells him. However, this sudden shift is only possible if he trusts his friend. This trust is the result of their history together. In other words, trusting his friend means that they are entangled. This shows us that a shared wave-function between him and his friend is what allows him to accept the word of his friend, and this acceptance is a spontaneous act that causes a shift in his awareness.

Wigner accepts what his friend tells him because they are closely entangled. If someone he never met before tells him the results of a test, he will probably reserve judgment until he knows more. This offers us a valuable insight into how entanglement is involved in the wave collapse process. And this can help give us an intuitive understanding of what is going on at the quantum level. (We will also see how this applies to the process of decoherence later).

In fact, we can take this further. Wigner is probably not going to feel much weight if he hears an unknown person telling him the result of a test. He will feel even less weight if the person says they did not actually see the test results themselves; they were just passing along what they heard from another person.

On the other hand, a lot more weight would shift Wigner's scales if he hears from fifteen people and they all report the same results, especially if they each say that they witnessed the test directly. And the weight will increase significantly if these fifteen people are well-known physicists, even if he does not know them personally. But the most weight will come from fifteen physicists that he knows and trusts. This shows how information passed along by a number of entangled relationships with others makes the outcome clearer to a third-person observer.

However, there is no way to predict when exactly the scales will shift to the point where Wigner accepts the information that he is hearing third-hand. We only know that when Wigner reaches that tipping point, and accepts the outcome of the experiment, that his realization does hit him suddenly. The shift in his perception happens all at once. He now feels confident that he knows what happened. This shows us clearly that this wave collapse is describing a shift in his perception. It is easy to see why this happens suddenly, because we all know what it means to "get" an idea. It hits us all at once like a light turning on. On the other hand, the influence from third-hand information grows gradually and, thus, describes a different process (decoherence).

This insider perspective is valuable for understanding human experiences. However, the scientific value we gain from this all depends on how similar human entanglement is to quantum entanglement. If they are identical processes, insights from human relationships can offer us a powerful way to make sense of the quantum world.

To illustrate this point further, imagine you are at a party when a physical knock-down fight starts between two people in another room. You are too far away to hear or see anything about what happened, but people soon start coming into your room and you overhear them talking about the fight. After a while, a few of your friends come by and pass on what they heard. Pretty soon some of the details become clear. You now have a sense of what happened.

This story is similar to Wigner's Friend, except there are a number of friends and quite a few strangers as well. This shows how third-hand information spreads and how a consensus story of what happened emerges. This is the process of decoherence. However, looking closer, we can see that only certain types of information consolidate to form a clear picture, such as who the fight was between and where it happened. This is objective information. Subjective information, on the other hand, remains vague, such as why they were fighting and who may have started the fight. QM faces this same problem.

It is easy to see why this happens at the human level: No observers actually saw who started the fight, and there was no way that observers could see why they were fighting because intentions and motivations are invisible to outsiders. Some of the words that the two fighters yelled at each other, after the fight started, may have been heard, but people could only guess at what those words meant because they were personal exchanges. Each observer guesses differently about the meaning and thus passes on a differently "colored" interpretation. These different interpretations conflict with each other – they do not converge, making it hard to consolidate them into a clear account.

The cause of the fight and the words that the fighters yelled at each other sprang from a personal relationship – from a shared space and history between them. Outside observers cannot see the inner dynamics of this relationship. That is why third-person observation forms no clear consensus about the motivation behind the fight. The public never really knows the emotions and feelings between close friends and lovers – or sworn enemies – in private relationships.

If this insight applies to quantum interactions, it changes the story completely. It suggests that the reason we cannot see quantum states directly is because these shared dynamics between sentient quanta are private, knowable only to those involved. This is why those dynamics are intangible, because no third-person view of them is possible. We will never get the full story with only outsider accounts. We can only guess. This allows us to relate to the behavior of quanta and understand their seemingly irrational behavior because human relationships are equally irrational when viewed from the outside. We know from personal experience that there is no definitive logic, and there are no fixed laws determining the outcome of relationships.

2.1.2 The Third Person Problem

The question being raised here is whether the lessons we learn about relationships at the human level directly relate to quanta. The only way to find out is to see how far these similarities go. And this is where Wigner's Friend gets interesting, because we find a similar story at the center of Rovelli's paper on "Relational Quantum Mechanics." He calls it "the third person problem." The difference is that Rovelli is talking only about what happens at the quantum level, while Wigner was describing the human level. Rovelli (2008) writes:

> By using the word "observer" I do not make any reference to conscious, animate, or computing, or in any other manner special, system. I use the word "observer" in the sense in which it is conventionally used in Galilean relativity when we say that an object has a velocity "with respect to a certain observer". The observer can be any physical object having a definite state of motion. For instance, I say that my hand moves at a velocity *v* with respect to the lamp on my table. Velocity is a relational notion…and thus it is always (explicitly or implicitly) referred to something; it is traditional to denote this something as the observer, but it is important in the following discussion to keep in mind that the observer can be a table lamp. Also, I use information theory in its information-theory meaning: information is a measure of the number of states in which a system can be – or in which several systems whose states are physically constrained (correlated) can be. Thus, a pen on my table has information because it points in this or that direction. We do not need a human being, a cat, or a computer, to make use of this notion of information. (p. 3)

In other words, Rovelli is using a purely third-person perspective for his analysis. Using this perspective means that he cannot see anything about the inside dynamic of what is happening. (Later we will see why his "Galilean observer" analogy falls short of what is needed because it is lacking the inside dynamics. It works fine for classical physics, but is not enough to represent the dynamics of quantum interactions). Next, Rovelli (2008) takes us through a formal analysis of what happens when an observer "O" makes a measurement on a system "S."

> For the moment we may think of O as a classical macroscopic measuring apparatus, including or not including a human being. Assume that the quantity being measured, say q, takes two values, 1 and 2; and let the states of the system S be described by vectors (rays) in a two (complex) dimensional Hilbert space H_S. Let the two eigenstates of the operator corresponding to the measurement of q be $|1\rangle$ and $|2\rangle$. As it is well known: if S is in a generic normalized state $|\psi\rangle = \alpha|1\rangle + \beta|2\rangle$, where α and β are complex numbers and $|\alpha|^2 + |\beta|^2 = 1$, then O can measure either one of the two values 1 and 2 – with respective probabilities $|\alpha|^2$ and $|\beta|^2$. (p. 3)

This will sound like gobbledygook if you are not familiar with quantum formalism. Later, I will explain why this method is used. For now, let me summarize what Rovelli is saying: If O makes a measurement of S, and there are only two possible outcomes of the test, $|1\rangle$ and $|2\rangle$, then quantum formalism says that system S is in a state where two possibilities exist at the same time (more about this in the next section). There is also a statistical probability associated with each of these possibilities, α and β, and if you add the squares of these probabilities together it will equal 1.

Rovelli then describes what happens when the measurement is taken (p. 3). First, system *S* is clearly affected by the measurement process, because after the measurement *S* is no longer in a state of two possibilities. There is now only one actual outcome. Therefore, the possibilities have collapsed down to one actuality.

Rovelli goes on to describe the same sequence of events, but this time from the perspective of a second observer "*P*" who does not perform any measurement. In other words, *P* is a third-person observer. This is where "the third person problem" comes from. This is like the story of Wigner's Friend, where Wigner was the third person.

The first thing that *P* observes is that *O* and *S* have formed an interaction with each other due to the measurement that *O* made on *S*. Rovelli says that *P*, as an outside observer, can see that *O* has a quantum state of its own and *S* has a quantum state of its own, and when they interact they form a joint quantum state. Another way to say this is that *O* and *S* become entangled through the process of measurement.

P also sees that *O* is influencing the outcome of the measurement. This means that the probabilities of the two outcomes are altered because *O* is now involved. This is important because it shows us that something is happening between *O* and *S*. They are affecting each other. But if we use only an outsider's perspective, we cannot see why this happens or what it means. An insider perspective suggests that the relationship between *O* and *S* influences the outcome of the measurement.

Rovelli then gets to the key point that he is trying to show: Because *P* is not directly involved in the measurement, *P* cannot see which of the two outcomes becomes the actuality. To *P*, the shared quantum state of *O*-*S* is still in a state where two possibilities exist at the same time. *P* does not know the outcome of *O's* measurement. Therefore, *P* only sees that the joint *O*-*S* state has changed.

Rovelli (2008) concludes:

> Thus, I come to the observation on which the rest of the paper relies.
>
> **Main observation:** In quantum mechanics different observers may give different accounts of the same sequence of events. (p. 4)
>
> If different observers give different accounts of the same sequence of events, then each quantum mechanical description has to be understood as relative to a particular observer. Thus, a quantum mechanical description of a certain system (state and/or values of physical quantities) cannot be taken as an "absolute" (observer-independent) description of reality, but rather as a formalization, or codification, of properties of a system relative to a given observer. Quantum mechanics can therefore be viewed as a theory about the states of systems and values of physical quantities relative to other systems…. Therefore, I suggest that in quantum mechanics "state" as well as "value of a variable" – or "outcome of a measurement –" are relational notions in the same sense in which velocity is relational in classical mechanics. (p. 6)

Rovelli concludes that quantum states and measured values are relative. None exist as *observer-independent* realities. But, why is this true? The reason, that we just saw with Wigner's Friend, is because there are inner dynamics taking place in private relationships between quanta that no third-person perspective can see. An outside observer cannot see the same thing as those who are directly involved. This is why different observers arrive at different conclusions about what has happened. Thus, reality is *observer-dependent*.

The only way *P* can find out the result of a measurement made by *O* is for *P* to interrogate *O*. This means that *P* has to make a measurement of *O* and *S* to find out what transpired between them. But, as soon as this happens, *P* is no longer a third-person observer. *P* is now directly involved. This means that *P* is also entangled, and this affects the relationship between *O* and *S*. Thus, a measurement means a wave collapse, and this is different for those involved than it is for outsiders.

All of this is perfectly consistent with the insights gained from the human level examples given above. Everything that happens is *observer-dependent*. Once again, the similarities between human experiences and the behavior of quanta go deep and appear to hold up under formal analysis.

2.2 Superpositions

The most important reason that physicists say quantumness does not extend much further than the realm of subatomic particles is because superpositions quickly disappear as particles interact with their environment. It is virtually impossible to find quantum level superposition states at the level of biological organisms. Thus, superpositions are the toughest test for the LoP Interpretation.

To understand superpositions, let us return to the two-slit experiment. If photons are sent through one at a time, and there are no detectors near the slits, then we have no way of knowing which slit the photons go through. If we run the experiment over and over, we will see an interference pattern develop from where the photons hit the screen. This tells us that the photons are not just going through one slit or the other. Something else is happening. It appears as if the wave-like nature of the photons allows them to go through both slits at the same time.

This is not just true for photons. Electrons and other fundamental particles will display the same phenomenon. Even atoms produce interference patterns. But as objects become bigger, the interference quickly fades. It becomes virtually impossible to see superpositions when objects are big enough to be seen with our eyes.

Quantum formalism says that we must treat the two slits as two possible paths to the screen and that both possibilities exist at the same time. In other words, it is as if the two possibilities are super-imposed on top of each other.

As Roger Penrose (2016) explains, we must not think of this as if there are two photons and each one goes through a different slit. If that is the case, we can apply the logical term "and" to describe what is happening. We cannot use "and" because there is only one particle. Also, we cannot apply the logical term "or" either. The photon does not simply go through one slit *or* the other, because we will not see an interference pattern if that is what is happening. Superposition is a unique state. This is not just because multiple possibilities exist at the same time, but because all those possibilities actually influence the outcome at the same time. This influence is what creates the interference pattern (p. 24).

If you roll a six-sided die, it will end up on one of its six surfaces. These six possibilities *do* exist at the same time before the die settles onto one surface, but the possibilities *do not* influence the outcome. The die simply lands on one of the six surfaces *or* another.

The idea of superpositions is so illogical that physicists needed a long time before they could accept them as real. The evidence now seems indisputable. Here is how Heisenberg (1959) explained this strange quantum behavior:

> This concept of the probability wave was something entirely new in theoretical physics… [It] meant a tendency for something… It was a quantitative version of the old concept of 'potentia' in Aristotelian philosophy. It introduced something standing in the middle between the idea of an event and the actual event, a strange kind of physical reality just in the middle between possibility and reality. (p. 42)

This is the concept of potentia that the "Taking Heisenberg's Potentia Seriously" paper is referring to. Let's look at some examples of superpositions.

Quantum theory says that an electron can exist in many different places as it moves through a conductor. The probabilities usually decrease with distance. This means that, from time to time, the possibility exists that an electron can appear on either side of an impermeable wall, if that wall is thin enough. One moment it can be on one side, and the next moment it can be on the opposite side without going through the wall. This is exactly what happens, and the principle is used to make transistors work. The process is called "tunneling" because it is as if the electron tunnels through the silicon wall. However, it does not actually tunnel, it just appears on the other side.

Or take the case of atoms. An electron does not orbit the nucleus like a planet orbits a sun because that would mean the electron is traveling a distinct path around the nucleus. It is not, and physicists know that it is not, because if it is, it would lose orbital energy and eventually descend into the nucleus. Instead, electrons are suspended in a stable energy state in relation to the nucleus, as I mentioned earlier. Quantum theory says the electron is in a superposition state of all possible positions in an electron shell around the nucleus. You can think of this as if the electron is a droplet of water that does not exist in one place because it is suspended as a gas in a cloud that surrounds the nucleus, except this cloud is a cloud of possibilities.

Why do quanta act this way? Why do superpositions exist at the quantum level? Quantum theory does not know, but suggests that it has something to do with quanta being wave-like when they are not observed. This means that an electron can literally be spread out across a region of space. It does not have to move through space to get to another location. It can leap there. The problem for this paper is that we never see organisms or human beings leaping around this way.

However, the story changes once we understand what superpositions are and why they exist. An insider lens, rather than an outsider lens, can help us gain insights into what superpositions mean.

The LoP Interpretation says that superpositions are not just possibilities – potentia: They are the possibilities that exist in relationships. For example, consider trying to choose which friend you should to go out to lunch with. You have two possibilities. Both options influence you and weigh on you. You can go to lunch with one friend or the other, or you might even consider taking them both to lunch at the same time, but a joint lunch date creates even more complications (interference patterns) because your two friends might not even like each other. The point is that, before you make a decision, all of the possible options influence you because you anticipate the way your relationships will be impacted by the choices you make. This is how possibilities in relationships influence us and shape our decisions.

Relationships are complex because they are open-ended, they are not deterministic. But as soon as we act on one of these possibilities – as soon as we choose one – the possible outcomes collapse down to one actuality. This is what is happening when the wave function collapses.

The reason we never see people in different locations at the same time is because we are looking at their bodies. Bodies are assemblies of billions upon billions of particles. Remember, according to the LoP Interpretation, quantum behavior only exists at the level where internal agents are involved in relationships. Quantum effects fade away when we look at huge conglomerates, such as a mound of dirt, because conglomerates have no ability to act as sentient agents. As a result, all of the possible relationships between particles in a mound of dirt cancel each other out.

For example, there are billions of electrons jumping around in the electron shells of the atoms of our bodies. What difference does this make to the position of our bodies? To make a detectable difference, billions of electrons would all have to leap in exactly the same direction at the same time. But this never happens because each leap is determined by one-on-one relationships, making it statistical. This is why bodies of organisms never appear to leap from place to place.

If superpositions do not exist at the level of human beings and other organisms, then the LoP Interpretation fails. Is this the death knell? Look closer. We never actually see electrons in multiple places at the same time either. Whenever we measure the location of an electron it is always in one place. Yes, we can detect the presence of an electron as it surrounds an atomic nucleus like a cloud, but we cannot see its specific location until we measure it directly.

Using this new understanding, the story changes when we look at human beings – not their bodies, but the intangible internal agents who inhabit their bodies. Can we, as internal agents, be in different places at the same time? Yes, we can, because we inhabit all of our body.

When we are upset by bad news, we feel it in the pit of our stomach. We cheer ourselves up by singing a song. Songs and emotions can move us. Where do they move us? To a different place than the pit of our stomach. Perhaps our heart center?

We also become aware of our heart center when we are with our lover. But when we think about the world, it seems as if we are looking at a screen in our heads. Sensations and sounds and feelings ripple through our bodies. At any moment, we can be anywhere in our body or be associated with our whole body at the same time. We are not limited to one place until we specifically move our attention there. Then we make a quantum leap to that place.

This might sound like nothing more than subjective impressions, but Roger Sperry's experiments (1968) with people who had the nerves cut between the left and right hemispheres of their brain (to prevent convulsions), prove that each hemisphere of the brain processes sensory information independently from the other. Sperry also showed that these people still used both the right and left hemispheres of their brain, depending on the situation. And when using one half, perceptions from the other side simply faded into the background, the same way we ignore sounds coming from another room when we are engaged in a conversation. In other words, we leap back and forth between the two hemispheres of our brain whenever we shift our attention (pp. 723-727). Sperry (1964) also showed that these people never felt as if they were split in two, and their families noticed no changes in their behavior. They and their families experienced them as the same single individuals they were before their operations (p. 46). Sperry won the Nobel prize for his research. (For a more complete review on this topic, see Marman, 2016, pp. 307-311).

Recent experiments have taken this further. They show that, when we consciously use what we see through our left eye and through our right eye to create a three-dimensional picture, our attention oscillates back and forth. We never consciously see through both eyes at the same time. Our attention can only be on one eye at a time. If our brain is just a computer, it should process the data from the left eye and right eye in parallel. In fact, it does exactly that in the early stages. But this process radically changes when vision becomes conscious, as Dehaene (2014) explains:

> [These experiments prove] that what matters to consciousness is not the initial stage of peripheral visual processing (where both [left and right eye] alternatives are still available) but a later state (at which a single winning image emerges). Because our consciousness cannot simultaneously apprehend two objects at the same location, our brain is the seat of a fierce competition. Unknown to us, not just two but countless potential perceptions ceaselessly compete for our conscious awareness – and yet at any given time, only one of them makes it into our conscious mind. Rivalry is, indeed, an apt metaphor for this constant fight for conscious access.
>
> Is this rivalry a passive process, or can we consciously decide which image will be the winner of the fight? When we perceive two competing images, our subjective impression is that we are passively submitted to these ceaseless alternations. That impression is false, however: attention does play an important role in the cortical competition process. (p. 30)
>
> But most important, the very existence of a single winner depends on our giving it our attention; the fighting arena itself, as it were, is made up of the conscious mind. (pp. 30-31)

In other words, conscious seeing is different from what happens in the early stages of processing visual data. The moment we consciously see, we view images from only one eye at a time. Visual data is processed in parallel before then, just like superpositions that exist at the same time. By moving our attention, it is just as if we are making a measurement. That is when only one of the two possibilities exists. Why one eye and not the other? It may be something seen through our left eye that catches our attention, or there might be something in the right eye's field of view that intrigues us. Or we go back and forth because we want to compare the two. In other words, images are not actually "competing" with each other, as if this is some kind of fight. These are relationship possibilities. Images from both eyes are unconsciously processed at the same time, but only one makes it to conscious perception. This appears to describe the wave collapse process. It shows us that only one possibility emerges and becomes tangible to our awareness at a time.

We are venturing into controversial territory here. Neuroscientists, including Stanislas Dahaene, whom I quoted above, generally see consciousness as something that emerges from the brain. On the other hand, many philosophers argue that this avoids the hard problem of consciousness, which is that there is an internal aspect of conscious experiences – the sharpness of a pain, the feeling of the warmth of the sun, or the yellowness of a lemon. First-person perception has an inner side to our experiences that is not easily communicated through verbal description. We cannot explain what the sourness of a lemon is like to someone who has never tasted it before. Dahaene (2014) writes:

> I disagree [with the philosophers], and I will argue that the notion of a phenomenal consciousness that is distinct from conscious access is highly misleading and leads down a slippery slope to dualism. We should start simple and first study conscious access. Once we clarify how any piece of sensory information can gain access to our mind and become reportable, then the insurmountable problem of our ineffable experiences will disappear. (p. 10)

When Dahaene says “conscious access,” he is talking about when the processed information in our brain crosses over into our conscious awareness. I call this the “threshold of perception,” and it plays a vital role in how spontaneous symmetry breaking and the wave collapse work, according to the LoP Interpretation. Dahaene says that studying how unconscious sensations cross over to become conscious has caused a revolution in cognitive neuroscience over the last 30 years. I believe that physics can gain the same benefit by applying this understanding to how quanta cross over from intangible possibilities to tangible actualities.

However, when Dahaene (2014) says that he disagrees with philosophers, it is not because he thinks that we should ignore the inner aspect of experiences. On the contrary, he says that accepting subjective reports as valid data has created “a revolution for psychology” (p. 11).

Once again, this is exactly in synch with the LoP Interpretation. Third-person measurements and observations will never be enough to understand the inner dynamics of relationships between sentient agents. This remarkable similarity between the unpredictable nature of the wave collapse and the indeterminacy with how living organisms make choices can be seen as evidence that there is an internal aspect to quantum mechanics that is remarkably similar to what psychologists have learned to accept.

Brushing such evidence away and saying that we simply live in a statistical world adds no value or meaning. It offers no insights leading to a deeper understanding. On the other hand, look at the amazing similarity between the way quantum superpositions collapse down to one actuality and the way countless sensations are processed in our brain in parallel and then reduced down to one relationship that is selected by our attention and then emerges into conscious awareness. If these two processes are not just similar, but the same, it opens new doors for neuroscience and physics.

Dahaene’s main disagreement with the philosophers is his concern that it leads down a slippery slope into dualism. He need not worry. The “Taking Heisenberg’s Potentia Seriously” paper (Kastner, Kauffman, and Epperson, 2017) shows that invisible quantum states do not exist tangibly because they cannot be observed directly. This means we should not treat them as objective facts. However, they are still ontologically real and have a measurable impact on the tangible actualities that make up the space-time dimension. Thus, the philosophical duality is no longer a problem because there is no gap between mind and body (pp. 3-4). The LoP Interpretation agrees with this.

We will get into more about all of this later. I have included this aside about neuroscience now only to show that once again we see a direct relationship between how the "countless potential perceptions ceaselessly compete for our conscious awareness" (Dehaene, 2014, p. 30). This describes the same way that superpositions reach out with open hands to become actualities. Only one can be grasped, and this is what happens when the wave function collapses or the symmetry breaks. One of the intangible possibilities crosses the threshold to become tangible.

For example, think about the relationships we have with our cells and organs. It is easy to forget about them, as they are unconscious until we get hungry or need to go to the bathroom. Then they cross the threshold of our perception. Our attention shifts suddenly if our heart beats erratically or we feel short of breath. In other words, the relationships between us and the cells of our bodies influence us with possibilities all the time. This is what it means to inhabit a living body.

Electrons appear to inhabit an atom the same way. They can be everywhere in an energy shell that surrounds an atom. They can also leap from one shell to another. They can spread out like a cloud, or they can be in just one place when they are engaged in a measurement.

Do we not experience this same bizarre quantum behavior in our lives? Where do we, as internal agents, sit in our bodies? As Dahaene (2014) points out, ancient philosophers asked where the seat of soul is, and they offered a wide range of answers: Hippocrates and Hierophilus said the seat of soul is in the brain. Democritus and Aristotle said that soul exists throughout the body. Epicurus put the seat of soul in the stomach, the Stoics within and around the heart. Strato placed the seat of soul between the eyes (p. 7).

They all seem to disagree. Now we can see why. They are all correct because we as an internal agent can move our seat of attention to any place in our body, or we can live everywhere in our body if we stop focusing our attention on any one spot. This is consistent with quantum behavior.

However, the most noticeable experience of superpositions, for human beings, comes from our relationships with other people. All of our relationships with others influence us at the same time. They are always there in the background shaping our lives, whether we realize it or not.

Should we move to another country to take a promising job if it means leaving our lover? Will we take time from a busy work day to buy a gift for our child's birthday? Which friend should we go to lunch with today? In other words, superpositions represent the possibilities in relationships – the "potentia" of what our relationships can become.

Therefore, it is valid to say that we live with the possibility of taking a job in another country, and we live with the possibility of not moving because living with our lover is too important. We live in both of these *states* at the same time. And it is clear that these possibilities *interfere* with each other. Both possibilities weigh on us until our scales tip one way or another. They do not force us. This is not about cause and effect. They only influence us. And the moment we act on one of the two possibilities, it becomes tangible and the other choice disappears – it is no longer an option.

This describes exactly what happens when the wave function collapses. It collapses only when one of the intangible possibilities is selected. It then becomes an actual, tangible event. An insider perspective shows us how relationships give birth to the objective phenomena of our natural world.

This passes the informal test of the LoP Interpretation's prediction that quantum effects should exist wherever we see living creatures forming relationships with each other. This test is by no means conclusive. However, as unexpected as this prediction is, there seems to be enough evidence to suggest that it might be worth investigating further. In other words, this interpretation might just be crazy enough – as Bohr put it – to be right.

All of the bizarre behaviors of quantum mechanics appear to exist in the relationships between life forms. If this is true, then biology, sociology, and psychology will never be hard sciences like Newtonian physics, because they are too close to the relationships between sentient organisms. Quantum effects may play a more important role in these fields than anyone has realized. This shows how a new interpretation of QM could revolutionize our understanding of these fields.

However, the devil is in the details, as the saying goes. Before we can rigorously test this interpretation, we need a much clearer model for how quanta behave. And before we can formulate a model, we need to deal with the nebulous subject of consciousness. So let's dive in.

3. The Problem of Consciousness in Quantum Mechanics

In the last section, we informally looked at the similarities between quanta and organisms from the bottom up. All of the bizarre behaviors of quanta appear to be present in relationships between life forms as well. This opens the door to a potentially deeper understanding of QM.

In this section, I want to informally consider this from the top down. If the relationships between quanta and living things are more than resemblances, if they are governed by the same principles, then top-down similarities need to hold up to scrutiny as well. And looking at this from the top down leads to a number of additional insights that help clarify the underlying principles involved.

As Wigner (1961) said, ever since the first fully rigorous formalism of QM, the problem of consciousness has dogged QM (p. 172). With all the latest experiments – and there are quite a few (such as Ma *et al.*, 2012, Jacques *et al.*, 2006, and Yu, S. & Nikolic, D., 2011) – that strongly suggest human observation is not the cause of the wave collapse at the quantum level, there still has been no finding that eliminates the possibility that consciousness is involved. For an overview of this situation, see Nauenberg, 2011.

The case is quite strong that human observation is not the cause of the wave collapse at the quantum level. But this does not mean that consciousness is not involved at the quantum level, and it does not mean that there is no collapse of superpositions taking place at the level of human observation.

Here is the problem: When two photons become entangled, each photon somehow "knows" the spin state of the other, even when they are miles away. How do they know?

An experiment by Dumé (2007) shows that if the path an electron takes through two slits becomes "known" by even one other particle, such as a nearby electron, the interference pattern fades by a measurable amount. If two or more particles "learn" the path of the electron, the interference pattern fades even further (pp. 3-9).

If there are enough particles near the slits that it is possible for equipment to learn the path that an electron takes with a high degree of accuracy, then the interference pattern disappears completely.

In other words, the real reason that the specter of consciousness looms over QM is because the spread of information is crucial to how quanta respond. However, most physicists wave away the role that consciousness plays by taking the same position that Rovelli (2008) took in treating information according to the principles of information theory, by saying that "information is a measure of the number of states in which a system can be – or in which several systems whose states are physically constrained (correlated) can be" (p. 3).

Unfortunately, this avoids the real problem. The issue is not about "the number of states in which a system can be," but how the information of those states spreads and alters quantum states. Why do quanta alter their behavior when they gain information? For example, why do photons hit different places on a screen depending on whether the environment "knows" which slit they pass through? The assertion that information is no more than "the number of states in which a system can be" does not make this problem at the heart of QM go away.

Further, Fields (2012) shows that to assume a "Galilean" observer (as do Rovelli and most physicists) makes the observer too "informationally impoverished" to work in quantum physics. A quantum observer must, at a minimum, be able to alter its state in response to information that it receives. Acting as a passive reference point is not enough (pp. 92-119).

Physicists know these issues well, but as soon as the "c" word is raised, their hands go up and they say: "Stop! Before going any further, define consciousness. If you cannot define it, it has no place in science." This is an understandable response because there is no consensus on how to define consciousness.

This normally leads to a highly contentious philosophical discussion, but I am going to avoid this quagmire because it is not necessary. All that we need to understand is what impact, if any, consciousness has on quantum interactions. I do not mean the impact of human consciousness on quantum interactions, but the impact of *sentience* on how *quanta* respond. Clarifying the way that consciousness affects the relationships between quanta offers us a path to finding a testable way of verifying or falsifying the role of consciousness.

3.1 How to Work with Something That Cannot Be Measured Directly

Isaac Newton faced a similar problem when he studied time. As Rovelli (2017) explains, Newton realized that there is no way to measure time directly. We can only compare the rhythmic timing of one process, such as the swinging of a pendulum, with the rhythmic timing of another process, such as the ticking of a watch, or the pulse from a heartbeat. Rovelli asks,

> Is this not somewhat circular? What does it mean?
>
> It means that we, in reality, never measure time itself; we always measure the physical variables *A*, *B*, *C*, … (oscillations, beats, and many other things) and compare one variable with another, that is to say, we measure the functions *A(B)*, *B(C)*, *C(A)*, and so on. We can count how many beats for each oscillation; how many oscillations for every tick of my stopwatch; how many ticks of my stopwatch between intervals of the clock on the bell tower….
>
> The point is that it is *useful* to imagine that a variable *t* exists, the "true time," which underpins all those movements, even if we cannot measure it directly….
>
> It was Newton who understood all of this: he understood that this was a good way to proceed, and clarified and developed this schema. Newton asserts explicitly in his book that we can't ever measure the true time *t*, but if we *assume* that it exists, we can set up an efficient framework to describe nature. (pp. 180-181)

We are in the same situation with consciousness because there is no way to measure it directly. However, not being able to measure consciousness – just like time – does not mean that it does not exist. After all, we know consciousness is real from our own experience. So, what if we *assume* that it exists? Can we use Newton's trick and observe the results of consciousness by comparing one function of consciousness to another?

3.2 Conscious Perception and Intentional Action

There happen to be two specific functions that are ideally suited for this comparison: perception and action. These two functions describe the receptivity and responsiveness of everything alive.

The reason these two functions are ideal is because they both play such central roles in the lives of organisms. And both are functions of consciousness that appear to be completely dependent on each other: Intentional actions are only effective when guided by conscious perception, and the accuracy of conscious perceptions can only be calibrated with intentional actions (through trial and error). No act of internal agency, such as the ability to hunt for food or avoid threats, is possible without both conscious perception and intentional action working together.

We cannot measure consciousness directly. There is no way to detect it with any equipment. But when we throw a bird up in the air and it does not fall to the ground, but flies away, we see the evidence of a sentient internal agent. Every display of internal agency in creatures is directly tied to the use of conscious perception with intentional action – receptivity with responsiveness.

The relationship between perception and action goes surprisingly deep. Roger Sperry (1952) describes it as the single most important lesson that he learned from his first studies of the brain. Listen to what he says about how difficult it is to find *any* way of explaining how thinking (mental activities) can move muscles (motor behavior):

> An analysis of our current thinking [about the relationship between mental activity and the brain] will show that it tends to suffer generally from a failure to view mental activities in their proper relation, or even in any relation, to motor behavior. The remedy

> lies in further insight into the relationship between the sensor-associative functions of the brain on the one hand and its motor activity on the other….
> Only after we have attained some understanding of the way in which the sensory and thought processes become transformed into motor activity, can we hope to comprehend their meaning and plan of organization….
>
> Utilization of this motor approach immediately helps us to view the brain objectively for what it is, namely, a mechanism for governing motor activity. Its primary function is essentially the transforming of sensory patterns into patterns of motor coordination. Herein lies a fundamental basis for the interpretation, direct or indirect, of all higher brain processes including the mental functions….
>
> Further support for this point of view may be found in the study of brain architecture. One searches the cerebrum in vain for any structures that seem to be designed for the purpose of forming, cataloging, storing, or emanating copies or representations of the outside world. If any scheme or plan at all is evident in the complicated fiber associations and nuclear interconnections of the brain, it is a design patterned throughout for governing excitation of the "final common (motor) pathways." …
>
> To the neurologist, regarding the brain from an objective, analytical standpoint, it is readily apparent that the sole product of brain function is motor coordination. To repeat: *the entire output of our thinking machine consists of nothing but patterns of motor coordination.* (pp. 296-298)

Coordination between perception and motor activity is not only a valuable way of understanding the function of the brain; it is just as central to the lives of the simplest cells with no brain at all. They need sensory perception to guide their movements, and they need movement to create a feedback loop with perception. Without both conscious perception and action working together, repeated intentional behavior is impossible.

In fact, perception and action – receptivity and responsiveness – play key roles at every level of biological life. For single-celled slime mold to work as a group when hunting for food, individual cells need to act in synchrony with each other, without a brain, while specializing their roles at the same time (Marman, 2016, pp. 358-362). How is this possible without perception? Clearly it is not. Perception is just as vital to the activity of bee hives and all forms of social activities.

If perception is so important in guiding the actions of living creatures and life forms, and actions are just as necessary for guiding perceptions and making them meaningful, then perhaps this relationship can offer insights into how quanta would behave if they are sentient. In other words, any sentience an electron possesses would be meaningless if this sentience did not guide it to respond in some way. Can this help us understand why receiving information (which is simply another way of describing the act of perceiving) alters the behavior of quanta? Yes, perhaps, but only if the top-down comparison holds up. We need a more detailed description of how this works.

The approach I am taking here is similar to recent developments in cognitive science that have produced encouraging results, as Dehaene (2014) explains:

> Throughout the nineteenth and twentieth centuries, the question of consciousness lay outside the boundaries of normal science. It was a fuzzy, ill-defined domain whose subjectivity put it forever beyond the reach of objective experimentation. For many years, no serious researcher would touch the problem: speculating about consciousness was a tolerated hobby for the aging scientist. In his textbook *Psychology, the Science of Mental Life* (1962), George Miller, the founding father of cognitive psychology, proposed an official ban: "Consciousness is a word worn smooth by a million tongues…. Maybe we should ban the word for a decade or two until we can develop more precise terms for the several uses which 'consciousness' now obscures."
>
> And banned it was. When I was a student in the late 1980s, I was surprised to discover that, during lab meetings, we were not allowed to use the C-word. We all studied consciousness in one way or another, of course, by asking human subjects to categorize what they had seen or to form mental images in darkness, but the word itself remained taboo: no serious scientific publication used it… With a few major exceptions, the general feeling was that using the term *consciousness* added nothing of value to psychological science. In the emerging positive science of cognition, mental operations were to be solely described in terms of the processing of information and its molecular and neuronal implementation. Consciousness was ill-defined, unnecessary, and passé….
>
> In the past twenty years, the fields of cognitive science, neurophysiology, and brain imaging have mounted a solid empirical attack on consciousness. As a result, the problem has lost its speculative status and become an issue of experimental ingenuity….
>
> The word *consciousness*, as we use it in everyday speech, is loaded with fuzzy meanings, covering a broad range of complex phenomena. Our first task, then will be to bring order to this confused state of affairs. We will have to narrow our subject matter to a definite point that can be subjected to precise experiments. (pp. 7-8)
>
> What counts as genuine consciousness, I will argue, is conscious access – the simple fact that usually, whenever we are awake, whatever we decide to focus on may be conscious… When we are fully awake and attentive, sometimes we can see an object and describe our perception to others, but sometimes we cannot – perhaps the object was too faint, or it was flashed too briefly to be visible. In the first case, we are said to enjoy *conscious access*, and in the second we are not (and yet, as we shall see, our brain may be processing the information unconsciously). (p. 9)

Conscious access is something that can be tested. Experiments have made it clear that unconscious processes play an important role in influencing what crosses the threshold of perception, but the act of attention is still needed to select the one possibility that crosses the threshold to conscious awareness. In other words, something more is going on than just the processing of information in the brain.

3.3 Three Levels of Human Cognition

To compare quanta with human beings from the top down, I need to describe three levels of human cognition. Each level displays a unique relationship between conscious perception and intentional action. Do these same three levels of behavior exist in physics? If they do, what does this tell us?

3.3.1 Level 1: Analytical Conscious Thought

At level 1, we see perception as something that we can think about. Intentional action is also something we can think about. As a result, we see a gap between perception and action, as if they are two independent processes. This is why we have the ability to think before we act. We can choose consciously when and how to act, and we can choose consciously which perceptions to ignore and which to use to accomplish an intentional goal.

This first level is what most people associate with consciousness and free will. And this is why the idea that quanta could be conscious sounds so absurd, because it seems ridiculous to suggest that quanta can think. And if they cannot think, how can they use perceptions to guide their actions? This would be a problem for the LoP Interpretation, if the top-down comparison between human beings and quanta does not hold up. However, as you might guess, analytical conscious thought is not as simple as it seems.

The problem is that when we approach conscious thought this way we run into the mind-body problem that philosophers have struggled with for centuries. This is exactly the slippery slope into duality that Dehaene was trying to avoid because it is fraught with all sorts of problems.

For example, how do we move our muscles by thinking about moving them? Do we direct the specific muscles that we want to move? Do we even know which specific muscles are needed to stand up and wave our hand? Even if we were able to figure out the exact order and timing sequence to go for a jog, do we actually direct our muscles this way?

Thankfully, the answer is no. Experiments show conclusively that even if we could find a way to consciously control each muscle in the right order, we would look like a broken-down machine jerking its way forward, because our thinking processes are way too slow. Fortunately, we do not control our muscles this way. In fact, the only reason we are able to run and move fluidly is because we do not analyze our individual actions. Analysis is paralysis, as the saying goes.

The same is true with our perceptions. As Wilson (2002) shows, our brain is flooded with sensory messages from nerve cells throughout our body (p. 24). Can you imagine how long it would take to sort through the millions of messages our brain receives every second? It would be impossible, because we simply cannot think about more than one thing at a time.

There is no way we can sort through and think about all of our sensations any more than we can consciously control every action of our body. That picture is a myth. However, it is a useful story that we tell ourselves because when we decide to raise our hand, our hand *does* go up. We *do* have the ability to choose between vanilla and chocolate ice cream. We know that on some days we clearly need to get ourselves up out of bed to go to work. We *do* need to make it happen.

Yes, we have some control and we can make choices. We also use perceptions to guide our actions, but exactly how do these things happen if it is not through conscious thought? I believe that understanding how the wave collapse works at the quantum level can help us understand how this works in our brains. We will get to that later. For now, the question is: Do we see this pattern of Level 1 behavior when looking at particles?

Yes, we do. In fact, this is directly related to the way classical physics sees the world. Just as we imagine that the actions of our bodies are caused by intentions and will-power, classical physics pictures material bodies as objects moved by outside forces. In fact, this is why the classical idea of forces makes so much sense to us. It is the same as pushing a cart with our body. We do that.

Newton's laws of motion are based on a cause-and-effect relationship. In the same way, analytical thinking sees perception as independent of action for the same reason – because we see ourselves as the cause. We think before we act. We use reason and logic to make intelligent choices. But we cannot see how we move our muscles or our body, and physicists cannot see forces directly either, only the results of forces.

Classical physics pictures particles, atoms, and material bodies as independent things with external forces acting on them. In the same way, analytical thinking pictures the organs of our body as separate from each other, with our mind controlling them and telling them when to act.

However, physicists now know that the classical view of the world is largely an illusion. Quantum mechanics shows us that this view is only an approximation. As soon as we look closely, this lens of perception falls apart. There is no definitive cause-and-effect process at the quantum level. Two quanta that appear to be separate can be entangled. They become coupled together in one quantum state. Even atoms that seem like hard bits of matter from a distance are only fuzzy balls of energy when seen at the subatomic level.

Neuroscientists have run into the same issue. There is no clear cause-and-effect process between thought and action. This is why they often say that free will may be an illusion (Harris, 2012). A convergence of brain activity peaks hundreds of milliseconds before we think we decide (Libet, Gleason, Wright & Pearl, 1983), suggesting that even a simple decision is far more complex than we realize, and our choices are influenced in significant ways by unconscious processes.

When it comes to conscious thought guiding actions, we never actually see this in brain activities or in living creatures. This is why Sperry said above that research suffers from "a failure to view mental activities in their proper relation, or even in any relation, to motor behavior." Conscious actions do not actually work this way. Thus, the resemblance to classical physics holds up, because classical forces and the idea of particles as bits of matter do not actually work this way either.

3.3.2 Level 2: Skilled Actions and Relational Learning

Psychologists now know that learning new skills involves a different process than the type of conscious analytical thought used in academic learning. Skills are learned through *doing*. Thinking often impedes the learning of new skills, showing that this is a different process.

John Flach, Professor of Psychology, and Fred Voorhorst a design engineer, (2016), illustrate skill-based learning by describing the process a child goes through when first learning how to walk, then how to skate on ice, next how to do a handstand, and finally how to walk on stilts. Each skill requires a "different type of coordination pattern," a different series of actions to achieve control. In other words, they each require a different relationship between perception and action to click into place. And the only way to truly master these skills is through trial and error (pp. 104-105).

Skill-based learning uses a loop that starts with a directed action. The child must try something. This leads to perceptual feedback, such as the child falling on their face or flipping over on their back. Then they try again, using a new approach. With each loop of trial and error, they gradually learn how to balance and how to move. Errors, in this process, are essential tools for calibration (pp. 76-86).

Skill-based learning, in the early stages, happens without analytical conscious thought. This is easy to see because children cannot explain how they balance on stilts. They have no clear conscious idea about how they walk on their hands or skate on ice. They just know how to *do* it. Acquiring new skills is all about learning how to *do* something. This is how intentional actions are learned (pp. 185-188).

Thought processes are not involved in this learning process, but they still play an important role. Each directed action, for example, when children initiate each trial and error loop, are directed by thoughts. They think, “What if I try this?” before making another attempt. However, the way they learn to balance on their hands is different from anything they have learned before, so they have no way of thinking that can tell them what they need to do or how to do it. They just “get the hang of it.” This is clearly not the same process as analytical thinking.

Skill-based learning has three major characteristics, according to Flach and Voorhorst (2016):

1. It is learning by *doing*. A teacher might help illustrate through examples, but learning comes from practice, practice, practice. In other words, it needs action.

2. It requires tight coupling between action and perception. It is only loosely coupled to abstract cognitive processes. This explains why the best athletes are often not the best teachers.

3. Skill-based learning is even more crucial in situations that are highly dynamic, such as walking on your hands while on a boat swaying in the ocean, or trying to walk on a high wire. Extremely rapid corrections are needed in these cases to maintain stability. There is not enough time to think about each correction. You need to know how to respond instinctively without thought. Professional athletes excel at this (p. 187).

Tight coupling between action and perception is the key point here. When learning new skills through trial and error, perception and action are so tightly coupled that there is almost no gap. It seems as if perception flows directly into action. Trying to insert conscious thought into the process will seriously impede early stages of skill-based learning. This is why children are faster at learning new languages and other skills; they do not think as much about the process.

People have used skill-based learning for thousands of years – long before the third-person lens of science prevailed – because it was the best way to learn new crafts and professions. If you want to learn how to become a blacksmith, a carpet weaver, an artist, or you want to know how to raise a family, you need practice and experience. And it helps to work with masters of a trade.

In fact, if we trace back all the aspects of knowledge that we teach in schools today, we will find that they all began with skill-based learning. For example, rational and logical thought emerged only after people learned how to write with linear words and sentences. And written language came from spoken language. And spoken language grew out of non-verbal communication.

No one teaches a baby how to talk. Toddlers learn it themselves by making sounds and hearing the sounds they make. They get to know their bodies the same way: They form working relationships with their muscles and cells through trial and error.

Jean Piaget (1929, 1930, 1955), the psychologist, documented the way babies, in their first year, start recognizing the difference between their bodies and other things. They learn what it feels like when they grab their toes. Grabbing and sucking on their toes, over and over, shows them that this feeling is different from someone else grabbing their toes, or from them grabbing something else, like a rattle, that is not their own body. Thus, an understanding of what belongs to their body, and what does not, emerges from the experience of doing things – all without thinking about it.[6]

In other words, everything that we consciously think about is built on a framework of skills. At the base of every thought, every idea, is a skill-based way of relating to things. For example, our sense of "grasping" an idea is directly related to our experiences with grasping objects.

Therefore, this second level of cognition underlies everything that happens at the level of analytical conscious thought. However, it is hard to picture quanta going through a process of skill-based learning. So, we need a simpler way of understanding this second level of cognition. Fortunately, the answer comes from what I said above: Babies get to know their bodies by forming working relationships with their muscles and cells. In other words, we learn new skills the same way we learn how to work with others: through the dynamics of working relationships.

Skill-based learning is, in fact, the way we learn to form working relationships with other people. Remember point 3 above: Skill-based learning is crucial whenever situations change rapidly. People are also highly dynamic. They change continually from moment to moment and day to day. So we must learn to keep changing how we see them if we want to work together effectively. As our partners evolve, our responses need to adapt as well. Logical rules will not help. We need to continually learn from our errors to keep our working relationships running smoothly.

Musicians playing in orchestras are a good example. They must coordinate their actions precisely. There is not enough time to think before responding (Baumeister, Masicampo, & Vohs, 2011, pp. 352-353). Tests show that they play best when they focus on the flow of music, not the notes. The same type of synchronization is needed for professional athletes playing as a team. They must learn to respond fluidly to each other, without thought. Contrived actions cause the delicate dance between perception and action to break apart. Actions then become stilted, not natural.

---

[6] By the age of two, most babies learn to walk and speak. Through games of "peek-a-boo," they discover that people and objects continue to exist, even when they are hidden from sight. They acquire visual depth perception through experience, and how to move their arms and legs. They recognize family members, and they learn that crying brings food. The amount of learning in their first two years is extraordinary, but it all happens unconsciously from actions they make, years before they understand how to think analytically.

Any attempt to use the process of cause-and-effect interferes with the dynamics of working relationships, because, for a team to be effective, responses need to be spontaneous and natural. People need to learn each other well. Breaking the tightly coupled loop between perception and action in order to control a team interrupts the flow of effective teamwork. In fact, trying to control working groups, rather than leading them, often limits their potential. Learning how to work together through practice, by doing things as a team, builds stronger teams.

At the human level, it is easy to see the difference between analytical conscious thought and the flowing receptiveness and responsiveness in healthy working relationships. For example, if we want to learn how to work with another person, should we dissect them to study their organs and brain cells? Of course not, because this could kill the person we are trying to work with. Taking people apart will never reveal the secrets of what makes them alive. Reductive analysis can teach us how clocks and machines work, but it will not explain how to work with other human beings.

We run into the same problem if we try to psychoanalyze a person or categorize their traits (such as education level, male or female, skin color), or if we try to study their behavior patterns. Third-person observations, like these, are poor choices if our goal is to learn how to work with them.

We learn far more by spending time with them, asking them how they see things, doing things together, working as a team, and seeing them as friends. Those are the best ways to know a person. Objective analysis is not much help. In fact, it gets in the way of relationships.

However, using a relational approach has a consequence: We are now involved. We have lost our objectivity. More importantly, what we learn is not who another person is by themselves. We only see and experience who they are when we are working with them. This is the same wall physicists run into when studying quantum mechanics. This is not a coincidence. It is a clue that we are on the right track. This is the paradox we are trying to solve.

The best way to form working relationships is by doing things together, not by reading books or logical deduction. We absorb a sense of others when working toward a common goal. It happens without analytical thinking. In other words, working with others teaches us how to let our actions and perceptions flow fluidly with them, without thinking about it. This is what makes relationships so difficult to describe with words.

Skills are learned by forming working relationships. All skills are based on a tightly coupled loop between perceptions and actions, and so are healthy relationships. Therefore, what this second level of cognition is showing us is how actions are carried out in synchronized ways. Skill-based learning is needed before analytical conscious thought is possible.

Do we see this same process in physics? Yes, this is similar to the wave collapse process at the quantum level – the process where tangible actions emerge from intangible quantum possibilities. As we will see later, actualized events, where the wave function collapses, requires the coupling of perfectly matched quantum wave functions. This means synchronization between quanta. Only then is an exchange of energy possible. The resemblance to working relationships is remarkable.

An important lesson to learn from our human experiences, at the second level of consciousness, is that actions and perceptions still seem different from each other, but they are so tightly coupled together that they form a receptive-responsive flow from one to the other. This suggests that quanta should be responsive to relational perceptions leading up to a wave collapse. No thought should be involved because that is not how consciousness displays itself at this level.

Another lesson is that both working relationships and learning new skills begin with sporadic actions. To an outside observer such actions can seem random and chaotic. But, to those involved, they are trials and errors. In other words, actions at this level are initiated to learn how to form a working relationship. As soon as a relationship forms, sentient agents are able to change the state of how they work together. The flow of water is a good example of this, because the on-going sharing of electrons – known as covalent bonds – allows water molecules to flow fluidly.

It is also interesting to note that with more intelligent organisms we see fewer apparently random actions. For example, if a grown person picks up a bow and arrow for the first time, their aim will probably be poor, but they will still draw on countless similar actions to guide them. Not so with a baby, who will just aimlessly throw the arrows around. However, as you look at less intelligent life forms, uncoordinated actions become much more common.

For example, Heisenberg, M. (2009) describes the way amoebae use their flagella to spontaneously change their direction until they find something of interest (p. 165).

Likewise, Rayner (2017) shows that fungi send out hyphae in many directions until a source of food is detected. *Circumspection* – looking around – precedes directional focus (pp. 53-54).

This suggests that we should see more spontaneous actions at the level of quanta. However, once relationships are formed, we should see clear patterns emerging from what appear to be apparently random acts. This, of course, is exactly what we see with interference patterns created by individual photons. This is a sign that relationships are guiding what is happening. (More on this later).

In summary, we do not see clear cause and effect at this level, the way we do in classical physics, because we are *not* dealing with conglomerates. This second level shows us how sentient agents work together to bring about the actions and events that define our tangible world. We see this with cells working together in organisms, and with organisms working together as teams. And the same process appears to take place at the quantum level as well.

3.3.3 Level 3: Embryonic Perceptions and Emerging Emotions

Before sensations and urges to act can emerge into conscious perception, they exist in a form that is too subtle to describe with words. For example, the moment we walk into a room filled with people, we unconsciously sense the consciousness in that room. Before we have a chance to notice details, we often feel something that draws us in or repulses us. We form impressions of strangers the same way, even before we see them speak or act.

Our first impressions are not distinct. They are vague and amorphous before they become clear enough perceptions that we can consciously think about them. We can picture first impressions as being on their way to becoming comprehensible, but they have not yet arrived at a state where they are distinct enough for our conscious mind to perceive. William James

(1899), the psychologist, gives us a glimpse into this process when he writes about the nature of apprehensions:

> The gist of the matter is this: Every impression that comes in from without, be it a sentence which we hear, an object of vision, or an effluvium which assails our nose, no sooner enters our consciousness than it is drafted off in some determinate direction or other, making connection with the other materials already there, and finally producing what we call our reaction. The particular connections it strikes into are determined by our past experiences and the 'associations' of the present sort of impression with them. (p. 157)

> A child will call snow, when he sees it for the first time, sugar or white butterflies. The sail of a boat he calls a curtain; an egg in its shell, seen for the first time, he calls a pretty potato; an orange, a ball; a folding corkscrew, a pair of bad scissors. Caspar Hauser called the first geese he saw horses, and the Polynesians called Captain Cook's horses pigs. Mr. Rooper has written a little book on apperception, to which he gives the title of "A Pot of Green Feathers," that being the name applied to a pot of ferns by a child who had never seen ferns before. (pp. 159-160)

Thus, when we see something for the first time, our unconscious makes associations with things that it knows. It looks for the closest match until it gets to know what it is actually sensing. It learns by forming a relationship with the new thing, whatever it might be. And it forms relationships by experiencing the impressions. It does not learn by thinking about it, like Level 1, and it does not learn by doing and acting, like Level 2. At Level 3, we learn from experience.

This is how children learn what an orange is when they eat one. They "get to know" what snow is by seeing, feeling, and tasting it. This is similar to learning a new skill, except the process at Level 3 is unconscious. There are no trials or errors because feelings and perceptions are still emerging. They are not distinct enough to act on or think about. We simply learn through experience – by being involved. Until they are clear, the meaning of oranges and snow cannot cross over into comprehension. We cannot make sense of them or relate to them. We cannot even frame what they are, which is why there is no way to consciously think about them or do something with them.

To get a better idea about how the unconscious works, we need to get closer to our raw experiences, by becoming involved in the experiences themselves, not by thinking about them. This process cannot be taught with words. However, reviewing a famous psychology experiment can help.

3.3.3.1 Cards that Play Tricks with Our Minds

Psychologists Jerome S. Bruner and Leo Postman (1949), from Harvard University, describe the results of an experiment that they ran on perception. Their experiment seemed simple: They asked subjects to watch a screen where they displayed images of playing cards.

At first, the pictures were flashed for such a short period of time that the subjects could not perceive what they were seeing. Gradually, the duration of the images was increased, until they were able to recognize the cards (pp. 209-210).

The subjects were told about this part of the experiment. What they did not know was that mixed in with the images of normal playing cards were cards that had the colors reversed: for example, a red six of spades and a black four of hearts (p. 209).

The first thing Bruner and Postman noticed was that normal cards were recognized much sooner than the reverse-color cards. Normal cards required about 1/36th of a second before they could be "seen." The cross-color cards needed more than 1/9th of a second – four times longer! (p. 210)

This makes sense, since the unconscious already knew what real playing cards look like from previous experiences (i.e., playing card games). Therefore, they already had a lens of perception – a way of seeing cards. That is why they could identify normal cards quickly. At the same time, they unconsciously sensed that something was strange about the six of spades and four of hearts. Their unconscious needed longer to figure it out, because it did not "know" those images. These wrongly colored cards did not just take longer to recognize, they also created odd distortions in perception before the subjects figured out what was happening (pp. 211-213).

Most of the people first "saw" the red six of spades as either a black six of spades or a red six of hearts. Some of them consistently saw the wrong color of the card, while others consistently misinterpreted the suits. In other words, their unconscious was trying to *associate* these cards with things that they knew. The unconscious sensed that it was seeing a distorted image. So it tried to correct the picture by substituting an image of what a real six of spades or six of hearts should look like. The appearance was so close to a real card that it guessed that it was a real card (p. 213).

However, the match was not quite right, and with experience the unconscious sensed this. It seemed to see that the traditional six of spades did not fit everything it was seeing, which is why it took so much longer to figure out what was going on with the mis-colored cards.

A number of people saw something stranger: The colors of the cards seemed to shift before their eyes. They could not understand what was happening, or how to explain what they were seeing. They described the cards as purple, grayish, rusty-black, or brown-black. Their words were often bizarre: "Lighter than black, blacker than red," "Black but redness somewhere. Blurred redness," "First black, then red, then black" (pp. 215-216).

Their unconscious was searching to find a way to relate to what they were seeing. It was weighing different *possibilities*. It moved from one possibility to another, switching back and forth. It was trying to *relate* to these cards. That is why the colors seemed to shift before their eyes.

This is when more than half of the subjects experienced a complete breakdown in perception. It did not usually last long, but they became so confused that they lost all sense of knowing what was happening. Here is what one person said:

> "I can't make the suit out, whatever it is. It didn't even look like a card that time. I don't know what color it is now or whether it's a spade or a heart. I'm not even sure now what a spade looks like! My God!" (p. 218).

Psychologists call this “cognitive dissonance.” The unconscious searches for a lens – a way of seeing – that it can relate to, but nothing fits. At this point, the conscious mind completely loses its ability to orient itself, making first-person perception impossible. This is the state of confusion. It happens when first-person perception breaks down and only the unconscious keeps working and looking for a way to relate. The person does not know what to *do* and they do not know what to *think*. However, the unconscious process of experiencing continues, so they continue to learn.

Remember, all of this was happening in fractions of a second, as the cards flashed by. Subjects could only think about what they saw after the cards disappeared. It was too fast for their conscious mind. Therefore, it was their unconscious that was shaping their perceptions, not their conscious mind. And the unconscious had not yet learned how to relate to these strange new cards.

Shortly after these breakdowns in cognition, the subjects started getting glimpses of a new way of seeing. One person reported, “What’s the matter with the symbols now? They look reversed or something.” Another said, “The spades are turned the wrong way, I think” (p. 221).

The upward pointing tip of a spade that they were looking for did not match the downward pointing tip of the heart that was there. Their unconscious could now see the mismatch, but their analytical thinking could not yet grasp the new lens to see what it meant. They needed to fully let go of their old way of seeing before they could find a new lens – a new way of relating. Can you see how bizarre and different the unconscious process seems compared to conscious thought?

Then, suddenly the shock of recognition hit them. Bruner and Postman calls this the “My God!” reaction, since they heard this over and over, at the moment it made sense. “Good Lord, what have I been saying? That's a red six of spades!” (p. 222).

The subconscious figured it out. No reasoning of the conscious mind was involved. Once the right way of relating is found to explain the strangeness, everything snaps into focus. This is the “Aha!” moment, when it crosses over into conscious access. A new lens of perception just formed.

This experiment gives us a glimpse of the unconscious process. It shows us that Level 3 works by forming relationships and associations, and it forms these relationships by getting involved in experiences. This is how embryonic perceptions and emotions emerge into clarity. First-person intentional actions and third-person conscious thought are not possible before this happens.

We are now entering into controversial territory. While psychology has made progress recently in better understanding the process of conscious access, the world of our unconscious that processes sensations and impressions before they become conscious, is hard to nail down because they are not yet conscious. As a result, we find a number of radically different theories on how to interpret the unconscious. This is similar in many ways to the radically differing interpretations of QM.

And the similarity does not end there. Emerging emotional feelings, before they are able to cross over into clear emotional responses, are not static. They evolve continuously, in a remarkably similar way to how quantum wave functions evolve. For example, if we walk into a bar, our initial impression brings an immediate sense of like or dislike, but these feelings change as soon as we start talking to the people there.

Physicists see coherent quantum wave functions acting the same: They continually evolve. There are no sudden transitions until there is a wave collapse at Level 2.

We often remember the sense of emotional attraction or repulsion that we felt when first meeting another person. The feeling might be strong or mild, but it begins to evolve as soon as we get to know them better. Our emotional response can change fluidly from dislike, to intrigue, to genuine interest, depending on what the other person says and how they respond to us.

These emerging feelings can also be marked by moments of conscious perception, such as when the person does something that surprises us. We then suddenly change the way we see that person. This is similar to a wave collapse. In other words, in that moment our half-formed feelings and perceptions cross over into Level 2. When this happens, the relationship possibilities shift suddenly and start evolving down a different path. This is the same pattern that physicists see when the wave function collapses.

Here is another interesting similarity: Our first impressions of an environment do not come from one or two specific perceptions. They actually seem to come from an overall impression from all of our unconscious senses, as if they all flood us at the same time. This is the same way superpositions work. They all influence us at the same time, often creating a range of conflicting feelings. First impressions affect us this way because they are still emerging; they are only the *possibilities* of perceptions. In other words, they are what Heisenberg called *potentia*.

Plus, each of the countless impressions influence us with a different weight, based on how close they are to being recognizable, the same way probabilities in QM are used to calculate the likely outcome of a measurement. Therefore, some unconscious feelings influence us more strongly than others, but all of these impressions add together. This way of describing our state of consciousness at Level 3 is remarkably similar to the behavior of coherent quantum states.

Embryonic emotions that have not yet emerged as clear feelings are often considered subjective, but they produce a real effect. When someone feels a sense of admiration for us, whether we are consciously aware of it or not, it changes our unconscious feelings towards them. If two people feel a sense of attraction to each other, it is far more likely that they will be drawn to each other, even if the feeling is unconscious.

Nothing that we see at this level is distinct or definitive. We only catch glimpses of what appear to be half-formed perceptions and feelings leading to a vague sense of attraction or repulsion.

Quanta experience attraction and repulsion in this same open-ended manner. It makes them more likely to move closer together or farther away. But, for tangible movement to occur, there must be an exchange of energy. That requires a Level 2 wave collapse. We see the same thing on the human level: We can only act intentionally when tangible perceptions emerge into consciousness.

How do we observe the inner dynamics of Level 3 if it is unconscious? Obviously, we cannot see it clearly. We can only sense it vaguely in the moments before it crosses over into conscious access. This is virtually identical to the issue that physicists face with coherent quantum states, because as soon as they measure a quantum state it is no longer coherent. In other words, how can we study the uncertain nature of quantum states when they change into something distinct as soon as we measure them? This goes to the heart of quantumness. This is why there are so many widely differing speculations and interpretations. The problem is the same for psychologists and neuroscientists who try to study unconscious processes before they become conscious.

As a result, physicists are divided into two groups: those who believe the quantum wave function represents something real and those who believe it is “merely a calculational tool for working out probabilities of the results of experiments…” (Penrose, 2016, p. 198).

The Copenhagen Interpretation, which is the most popular interpretation of QM, says that the wave function is just a mathematical tool. However, there is significant evidence suggesting that it does indeed represent something real, as Roger Penrose (2016) points out, because some experiments are 100% accurate (such as retesting the spin state of a photon after it was just tested) (pp. 198-204).

The “Taking Heisenberg’s Potentia Seriously” paper also says that the wave function represents something real, and it offers a detailed model for how it influences every tangible and measurable event in our universe. This model, the paper claims, is what has been missing. The LoP Interpretation suggests that what has been missing is how closely quantum states resemble unconscious behavior. This explains why we see two states of reality: the quantum state and the visible, tangible world.

It turns out, as you might guess, that psychologists are also divided into two groups as well: those who see consciousness as simply a by-product that emerges from the brain, and those who see it the other way around – where consciousness shapes brain functions. Both sides face challenges.

For example, if conscious awareness emerges from brain activity, how do chemical and electrical interactions between neurons make the leap to consciousness? This question is not even close to being resolved. In fact, there is no good theory for how such a leap to consciousness could even be possible, as the neuroscientist, Sam Harris (2011), explains:

> Most scientists are confident that consciousness emerges from unconscious complexity. We have compelling reasons for believing this, because the only signs of consciousness we see in the universe are found in evolved organisms like ourselves. Nevertheless, this notion of emergence strikes me as nothing more than a restatement of a miracle. To say that consciousness emerged at some point in the evolution of life doesn't give us an inkling of how it could emerge from unconscious processes, even in principle....
>
> Consciousness – the sheer fact that this universe is illuminated by sentience – is precisely what unconsciousness is not. And I believe that no description of unconscious complexity will fully account for it.... Consciousness may very well be the lawful product of unconscious information processing. But I don't know what that sentence means – and I don't think anyone else does either. (Harris, Oct. 11, 2011)

Harris' readers were surprised by his comments. They asked him: Why does the emergence of consciousness pose such a problem? In a follow-up blog post, Harris answered: "Why is consciousness more perplexing than language or digestion? The problem...is that the distance between unconsciousness and consciousness must be traversed in a single stride, if traversed at all" (Harris, Oct. 19, 2011).

You cannot get to consciousness gradually. The step is immediate – it happens in one sudden leap. You are either conscious or you are not. There is no in-between. Nothing known to physics or chemistry can create a discontinuous leap like this, except for a wave collapse. But quantum effects have been ruled out by neuroscientists because they should not be visible at the level of evolved organisms. (See: Harris, 2012, pp. 29-30, and Dehaene, 2014, pp. 263-264).

The other side of the debate faces a similar challenge: How does consciousness influence our world of matter and energy? There is no evidence of other forces than those identified by physics. And why do matter and energy exist on one hand and consciousness on the other? This is the slippery slope into dualism that Dahaene mentioned earlier.

This certainly seems to be as difficult to solve as the emergence of consciousness. However, an explanation for how this is possible emerges from the LoP Interpretation. It will be explained in section 4.9. This is a benefit that comes from identifying underlying principles that can explain the formalism of QM. If the LoP Interpretation is right, then consciousness *does* come first, and quantum leaps *are* involved. This overturns the "compelling reasons" that Harris stated above: "the only signs of consciousness we see in the universe are found in evolved organisms like ourselves." This argument fails if we can now see signs of sentience everywhere, even at the level of quanta. Plus, wherever we see relationships between sentient agents we find quantum effects.

We will explore this in more detail later, but the point here is that we see, once again, a remarkable resemblance between unconscious processes that exist before conscious access, on the one hand, and pure coherent quantum states that exist before measurements, on the other.

3.3.3.2 Automatic Responses that are Not Automatic

Before we leave this third level of cognition, there is something I want to examine more closely. How do we explain embryonic unconscious feelings that are on the way to becoming distinct emotions? How should we treat first impressions on the way to becoming clear perceptions? How are we supposed to think about half-formed emotional feelings that are precursors to actions?

For those who believe that consciousness emerges from the brain, it is natural to describe these as nothing more than brain functions. In other words, they do not see these as results of consciousness. But this avoids the fact that at this level we see a display of half-perceptions and half-urges-to-act that are so close together that they, for all practical purposes, happen at the same time. In other words, we see receptivity and responsiveness – the very traits that are functions of consciousness.

Our first impressions arise immediately from a flood of sensations that permeate us when we enter a bar or meet a stranger. There is no time for analytical thought. There is not enough clarity to recognize one emotion to act on. This is what makes this third level unique and different from the other two states of cognition: Perception and action are inseparable because they are possibilities.

The receptivity and responsiveness that takes place at Level 3 has all the traits of being embryonic perceptions and emotional responses, both happening at the same time. Psychologists might call these “automatic” responses, the same way physicists see the behavior of quanta as automatic, but in both cases the term “automatic” *does not fit* because it implies cause and effect. In both cases, that is clearly what is *not* happening.

Physicists have proven this at the quantum level. Cause and effect requires an object to obey the force that is moving it. However, that is clearly *not* what happens at the quantum level, and that is clearly *not* what we see with unconscious processes before they cross over to conscious access.

In Newtonian physics, determination is possible because we can know the position and momentum of an object, and the forces being applied to inert objects appear to be separate. At the quantum level, however, the more accurately you know the position of a particle, the less you know about its momentum. If you know exactly where it is, then you have no idea where it is going. This uncertainty is inherent, making it impossible to predict what a single quantum will do.

For the same reason, we must abandon the idea of cause and effect when dealing with unconscious processes that lead up to and influence what crosses over into conscious access. Uncertainty rules over all of these half-formed perceptions and half-formed urges. More importantly, this third level of cognition shows us receptivity and responsiveness – two functions of consciousness – working together. This is how the unconscious learns to relate through continued experience.

Our first impression that we like someone is not automatic. It makes no sense to compare this to a mechanical reaction. The “chemistry” we feel with another person is not a chemical reaction because it is completely unpredictable. There is no evidence that chemistry in a relationship is the result of actual chemistry or external forces. Calling them automatic is simply avoiding the display of consciousness that we see at this level.

This is, of course, exactly the same thing that physicists do when they push aside consciousness. This is why Rovelli says that the “observer” does not need to be treated as conscious. A table lamp can be an observer, he says. But when we look at what is happening at the quantum level, we have no way of knowing how an individual quantum will respond to the information it receives. We can only make statistical predictions. This means that even the atoms of a table lamp form relationships with quanta in a way that suggests there are inner dynamics involved in the relationship. Quanta act as if they spontaneously choose one of the possibilities for no external reason.

All of this leads to a highly controversial conclusion, which is debatable and should be debated. However, if the LoP Interpretation is right, then unconscious processes must be considered an aspect of consciousness, just as the unpredictable behavior of intangible quanta must be seen as the result of sentience. We cannot see consciousness directly, but we can easily see the difference between automatic cause-and-effect reactions and the gradual evolution of relationships that develop through receptivity and responsiveness.

3.3.4 Comparing the Three Levels

Roger Penrose (2016) recently explained the problems with current interpretations of QM. His description so closely resembles the three levels of cognition discussed above that it is worth reviewing.

He starts by presenting a picture that can be seen as a simile of the physical world. In the picture, we see a mermaid sitting on a rock with half of her body above water and half below. He writes:

> The lower part of the picture depicts what is happening beneath the sea, as an entangled mess of activity involving many odd-looking creatures and alien entities, but with perhaps a kind of special beauty of its own. This represents the strange and unfamiliar world of quantum-level processes. The upper part of the picture depicts the kind of world that we are more familiar with, where different objects are well separated and constitute things that behave as independent objects. This represents the classical world, acting according to laws we have become accustomed to, and had understood – prior to the advent of quantum mechanics – as precisely governing the behavior of things. The mermaid herself straddles the two, being half fish and half person. She represents the link between the two mutually alien worlds. She is also mysterious and apparently magical, as her ability to form her link between these worlds seems to defy the laws of each. Moreover, she brings, from her experiences of the world beneath, a different perspective on our world above, appearing to look down upon it from a great height from her vantage point on the rock. (p. 138)

In other words, the classical world represents a world of definitive objects governed by cause-and-effect processes. The quantum world is an alien world to us because things are entangled, not clearly defined, and hidden from view. The mermaid embodies a third reality that in a magical way crosses from the undersea world into the visible world above the surface of the water.

This offers a great overview of the world as seen by our current understanding of physics. And it is easy to recognize that much of what makes the mystery so intriguing is that the mermaid's magic resembles so closely the mystery of how our unconscious crosses over into consciousness. However, the reason Penrose is using this simile is because he wants to help explain the underlying problem that QM faces. He goes on to say:

> It is the normal belief of physicists – and it is my own belief also – that there should *not* be fundamentally different laws governing different regimes of physical phenomena, but just *one* overriding system of fundamental laws (or general principles) governing *all* physical processes. (p. 138)

> Accordingly, the [classical and quantum] worlds…should not be thought of as really being alien to one another, but with our present understanding of quantum theory and its relation to the macroscopic world, it is merely a convenience for us to treat things as though they inhabited different worlds and thus obeying different laws. In practice, it is certainly the case that we *do* tend to use one set of laws for what I shall refer to the *quantum level* and another set for the *classical level*. The borderline between these two levels is never made very clear, and there is the common view that classical physics is, in any case, merely a convenient approximation to the "true" quantum physics that is

> taken to be satisfied *exactly* by its basic constituents. It would be taken that the classical approximation normally works extremely well when there are vast numbers of quantum particles involved. I shall be arguing later that there are, nevertheless, certain severe difficulties involved in holding too strongly to this kind of convenience viewpoint. (pp. 140-141)
>
> The classical world seems indeed to be extremely closely governed by the classical laws of Newton, augmented by those of Maxwell to describe continuous electromagnetic fields, and those being further augmented by the Lorentz force law which describes how individual charged particles respond to electromagnetic fields. If we consider matter in very rapid motion, we need to bring in the laws of special relativity, and when we involve sufficiently significant gravitational potentials, we need also to take into account Einstein's general relativity. These laws combine into a coherent whole, in which behaviour is governed…in a precise deterministic and local way. (p. 141)
>
> The quantum world, on the other hand, has a time evolution…described by a different equation, called the *Schrödinger equation*. This is still a deterministic and local time evolution…and it applies to a mathematical entity called the *quantum state*, introduced into quantum theory to describe a system at any one moment. This determinism is very similar to what we have in classical theory, but there are various key differences from the classical evolution process.... In fact, some of these differences…have implications that are so alien to our experiences of the actual behaviour of the world that it becomes totally unreasonable to try to continue to use [quantum laws] for our descriptions of reality after macroscopically discernible alternatives become involved. Instead, in standard quantum theory, we adopt a third procedure, called *quantum measurement*… performing this necessary link connecting the quantum world with the classical world of our experiences… [This] procedure is completely different from the deterministic evolutions of either [the classical or quantum levels], being a *probabilistic* action, and…it exhibits curiously non-local features that defy all understanding in terms of the classical laws that we are familiar with. (p. 142)
>
> However…there are some profoundly mysterious puzzles involved in the adoption of such a point of view, and it becomes very hard to accept that the strange [quantum]-rules, when directly applied to macroscopic bodies, can in themselves result in [collapse]-like or [classical]-like behaviour. It is here that the serious difficulties in “interpreting” quantum mechanics begin to loom large. (p. 144)

In other words, one of the fundamental unsolved problems of QM is why we see the world operating at three different levels. Most physicists realize that this does not seem right, that there should be a single perspective that makes sense of all three. The view we gain from psychology gives us an insider view that adds depth and meaning. But it still leaves us wondering why we see three levels.

I believe that this picture can be simplified.

1. The top level is defined by objective **third-person perception** of the world, where we see objects and actions as outsiders. Our analytical ideas and thoughts seem distinct and clearly defined, the same way that objects and forces appear distinct. However, a closer look shows us that nothing is as definitive as it seems. And this top level cannot explain quantum states or the states that allow creatures to be alive.

2. The most notable feature of the middle level is defined by **first-person perception**. This is what enables quantum states and unconscious processes to cross over into actualized events and conscious access, making them visible to third-person analysis. This is the source of all tangible activity. Internal agency originates at this level, allowing quanta and living organisms to act as individuals and exchange energy.

3. The bottom level is shaped by the influence of possibilities in relationships between sentient agents, whether they are quanta or living creatures. These possibilities are uncertain. They are never clearly defined, and they continue to evolve gradually. Attraction and repulsion emerge from the intangible dynamics of the relationships between agents. These dynamics are composed of wave functions, according to QM. At the human level we know them as receptiveness and responsiveness. They are the results of embryonic perceptions and urges-to-respond that are so close to each other that they appear to be two sides of the same coin. I call this **second-person perception** because, when writing a personal letter, we use the second-person voice to address the quality of "you" we sense in another being, forgetting ourselves in the process. This can also be called the relational lens of perception. This is why Rovelli was right to say that the quantum world is made up of nothing but relational states and values, but we must remember that these relationships are energized by inner dynamics that are intangible and invisible to outside observers.

This is a simplified summary of the lenses of perception that give the LoP Interpretation its name. All other lenses are composed of one or more of these three lenses. And from these three lenses, we can develop a model that is consistent with quantum formalism. It is also consistent with everything we know about psychology and neuroscience, as far as I can see.

The world forms and develops according to these three lenses because quanta are sentient. Thus, these three ways of seeing become the ways that sentient entities develop relationships with each other. This is why we see the pattern of quantum behavior at the level of human psychology and living organisms. Internal agency and the quantization of energy and matter is the result of first-person perception. The strange and irrational behavior of quantum and unconscious states comes from second-person ways of relating. And the classical view only sees the outside – the end result.

This represents an overview of the proposition presented by the LoP Interpretation. Next, we will study the underlying principles of perception that lead to these three lenses and quantum behavior.

4. The Creative Process of Perception – The Principles

In the last few sections, I have used an informal approach to compare quantum-level processes to organisms. The main purpose was to see if there was any obvious reason for ruling out the LoP Interpretation. I have found none, but of course all of these issues could be explored in far more detail. However, now is not the best time for debating these points. Once I lay down the underlying principles that allow a rigorous comparison with quantum formalism, then we will be able to do a much better analysis.

This section begins a more formal process. I will explain the fundamental principles of the creative process of perception that applies to both quanta and life forms, and I will explain how I arrived at them.

My goal is to show, first, how the sentience of internal agents naturally leads to embryonic perceptions and responses, and, second, how those emerging perceptions and responses lead to dynamic relationships. Then I will show how relationships can create the natural world of matter, energy, space, and time. In other words, we will see how the tangible universe emerges from nothing but consciousness – the same way that unconscious processes emerge to produce our conscious reality.

An even more rigorous process starts in section 5, where I show that the principles of perception explained in this section explain why quantum formalism takes the form that it does. Along the way we will see a number of additional insights emerge from these principles.

One of the lessons learned in previous sections is that comparing quanta with organisms gives us two different perspectives. At the level of quanta, where states and behaviors are simple, with only a few degrees of freedom, it is easier to see what makes quantumness so bizarre. From the level of living creatures, on the other hand, we see an insider point of view that offers a deeper understanding of what is happening to cause such irrational goings-on.

In this section, we are going to use this same process of going back and forth between quanta and organisms, but for a different reason: to identify key principles of perception. In describing these underlying postulates, we need to apply constraints from both ends of the spectrum, to make sure these principles work for both.

This should make it easier to find a way to invalidate the LoP Interpretation, if there is one, because more constraints need to be applied here than for any other interpretation. At the same time, these added constraints also make the LoP Interpretation more detailed in its explanatory power for what is happening at the quantum level.

There is an additional constraint that weighs heavily on the LoP Interpretation. If consciousness does indeed come first, before matter and energy, this means that these principles need to explain how mass and energy emerge, along with space, time, and everything else, for that matter. If the LoP Interpretation cannot show how our tangible world emerges from nothing but consciousness, then we will end up with a theory that still leaves us with a world of duality. It might offer added insights, but we will still be left with Roger Penrose's (2016) concern:

> It is the normal belief of physicists – and it is my own belief also – that there should *not* be fundamentally different laws governing different regimes of physical phenomena, but just *one* overriding system of fundamental laws (or general principles) governing *all* physical processes. (p. 138)

This additional constraint suggests that the LoP Interpretation must offer an explanation that starts before the world of matter, energy, space, and time emerged. In this simple starting point, only consciousness exists.

This is where I will begin, as I now introduce the first postulate:

4.1 Postulate 1: Consciousness Always Belongs to a Sentient Agent

This assertion, that consciousness always belongs to a sentient agent, can easily be debated. But there is no need to argue over this postulate, since it is nothing more than a starting assumption to develop a system of principles. As Bowman (2008) says in his book about quantum formalism,

> A postulate is, essentially, a statement made without proof or analytical justification – an underived statement. In physics, a postulate is, in effect, a proposal, and such a proposal must ultimately stand or fall not on *derivation*, but on *verification* in the physical world. It must be tested experimentally. Newton's laws of motion were such proposals. (p. 6)

The main reason for asserting Postulate 1 is because everything we have seen so far, at the levels of both quanta and organisms, suggests that sentience gives both particles and living creatures an ability to act as individuals through internal agency. This explains why matter and energy are quantized and why there is no such thing as an organism that is half-alive.

This is also consistent with Roger Sperry's (1968) research on people who have the connection between the two hemispheres of their brain cut: They retain their awareness as a singular person. And it is consistent with the discovery cited earlier that we must place our attention on something before it can cross over into conscious access.

Whenever consciousness plays a role, it does so through sentient agents whose actions are guided by perceptions. This is, therefore, stated as a starting assumption for the LoP Interpretation.

Another way of putting this is that consciousness always belongs to "someone." This means that consciousness does not float out in space on its own. Whenever we talk about consciousness we can always ask "whose consciousness?" As we will see later, this is an important constraint.

4.2 Postulate 2: Sentient Agents Can Experience Each Other

If, in the beginning, there is only consciousness belonging to one sentient agent, then how could it ever become aware of anything outside of itself? It seems absolutely necessary that there must be more than one sentient entity if relationships are going to create a world filled with material bodies and forces.

As soon as there is more than one sentient agent, then the possibility exists that they can experience and perceive each other, making it possible for relationships to form between them.

The experience of others leads to what might be called the first true perception. By perception, I mean an experience that is recognized. In this case, the first perception would come from the experience of something outside of the sentient agent's own consciousness.

What is the basis for this perception? The perception arises because there is a difference between self and others. If this difference is noticed, it can be perceived. If it is not noticed, the two sentient agents will pass each other like ships in the night and nothing will happen.

4.3 Postulate 3: Perception Begins with the Sensing of Differences

Psychologists say that all sensations that lead to perceptions are based on differences, such as the difference between hotter and colder. However, we need to be careful here. We do not want to base these principles on human perceptions because humans do not exist yet in the primordial world where there are only sentient agents who perceive each other.

Our human concept of differences comes from looking at the world as an outside observer. We sense that a pot is hot when we touch it because it is hotter than the countertop or the air. Unfortunately, outer perceptions do not exist yet in our fictional primordial world. This means that there are no such things as third-person perceptions yet. **The only perception that exists is first-person perception**, which comes from the experiences that belong to sentient agents.

Therefore, a sentient agent is able to recognize the presence of another sentient agent only because the experience of its own self is different in some noticeable way from experiencing the presence of others. This experience can lead to perceiving the difference between self and others.

Here is another place where we need to be careful. This first perception of the difference between self and others should not be seen as anything even close to a thought of any kind. At best, it will start out as an emerging perception. This is important because it means that the only level of cognition that exists up to this point is Level 3 – the unconscious – which is also what physicists call “the pure coherent quantum state.” There are no measurements possible yet and there are equally no distinct states or perceptions either.

If the first embryonic perception arises from experiencing the presence of another because it seems different in some way from the experience of self, then, in some cases, this half-formed perception should evolve and grow. Why would it evolve? There are three reasons:

First, an agent that starts to perceive the presence of others may want to know more about what this half-formed perception means. In other words, their first impression of others may spark a half-formed feeling of attraction. This is a display of consciousness at its simplest form: half-formed perceptions leading to half-formed emotional responses.

Second, the perception will evolve when the experience of another continues. If the sense of otherness only exists for a moment and then disappears, the vague perception cannot evolve. Or if there is no interest – or feeling of attraction – in the experience of others, then nothing will happen. But, if the agent feels some emerging sense of attraction from an incipient perception of another, and if this experience continues, then the perception should grow, as the unconscious learns how to relate.

Third, the most important reason that the perception of another will evolve is because the moment a perception begins emerging, the experience becomes more vivid. In other words, recognizing a perception heightens our awareness of that perception. The moment you sense a distinction of any kind, it becomes clearer to you. Becoming aware of something actively changes your experience of it as you get to know that experience. This shows us the creative power of perception.

This creative property of perception is the key to all of the mysterious behaviors of quanta.

Notice that third-person perception does not work this way. The outside world appears to exist as an independent reality from us. We appear to be mere witnesses. Observing does not seem to change the outside world or create anything. However, this is not true for embryonic perceptions.

At the level of cognition (where perceptions are just emerging and our urges to know are only half-formed), the instant we sense a difference, it becomes clearer. Recognition energizes the sensation, you might say, awakening a stronger feeling of curiosity and attraction. As a result, perceptions continue to gather strength and become clearer at the unconscious level.

If this is true at the human level, then the same process should be true at the level of quanta. This creative property of perception needs to be stated as a postulate:

4.4 Postulate 4: Perceiving a Difference Strengthens the Awareness of that Difference

As I said before, in reference to the unconscious level of cognition, embryonic perceptions can immediately trigger half-formed responses, as if the perception and response are one and the same. Now we can see why: The first glimmer of perception strengthens our awareness of that perception because it triggers an incipient emotional response. This response heightens our awareness. And, when the perception is strengthened, this triggers the response to grow in a way that is inseparable from the perception. In other words, it creates an increased feeling of a need to know more.

I have described the evolution of this process as if it begins with perception and is followed by an emotional response. In other words, receptiveness leads to responsiveness. We can just as easily see this process beginning with an emotional urge that then energizes our awareness of that urge, awakening an emerging perception. For example, think about times when you react unconsciously without thinking about what you are doing. It can awaken you to a sense of attraction or repulsion that you are feeling but had not noticed before.

In none of these cases are we talking about anything even close to cause-and-effect reactions. It would be more accurate to say that emerging perceptions can awaken emotional responses and embryonic emotional responses can awaken perceptions. This is how consciousness displays itself at the quantum level, which is also the unconscious level.

This is why sentient agents alter their responses based on perceptions (information). If perceptions and responses did not awaken each other, there would be no sentient agency.

For example, let’s say you are trying to listen to someone over the noise of a crowd. You may be completely unaware that one of your friends is standing in the back of the room. However, at some point a vague perception grows, or perhaps a vague feeling emerges that continues to grow stronger as your eyes continue to catch glimpses, because the emerging perception and feeling strengthen each other. Things change the moment you consciously recognize your friend in the back of the room. That is when it grows strong and clear enough to cross over into conscious perception.

Therefore, this fourth postulate tells us that embryonic perceptions and urges strengthen each other. And as they grow stronger, first-person perceptions and emotional responses become clearer.

Look closer at what this means: The first glimmering perception and feeling of your friend grows and evolves because your friend is there in the back of the room. This is the only reason perception and feelings grow clearer and stronger. In other words, when perceptions and feelings relate to something real, our perceptions and feelings continue growing and evolving.

This strengthening process of perceptions and feelings falls apart if the sensed differences do not exist in the first place. In other words, there can be no positive reinforcement if a perception or feeling is about something that is not really there. So, the distinction, or at least the hint of a difference, must be based on something real for a perception to grow stronger and clearer. And there must be an “interest” – an internal sense of attraction or repulsion. The strength of this interest, therefore, acts as a weighting factor, determining how fast the perception grows clearer and stronger.

From the above four postulates, we can now describe how the inner dynamics of second-person relationships develop and how they influence sentient agents.

4.5 Postulate 5: Second-Person Relationships Are Created by the Reinforcement of Shared Perceptions and Feelings

Up until this point, I have only spoken about the emerging perceptions and incipient responses of a single agent. Therefore, no relationships have formed yet. There are only first-person perceptions and feelings.

However, as soon as two agents both sense a common interest in each other, a new dynamic arises. At first, the embryonic perceptions and feelings evolve on an individual basis as before, but now something new emerges: the perception or feeling that they both share an interest in each other. This is a very different type of perception and feeling. It awakens a new emerging awareness of their mutual interest in each other. As a result, two agents can reinforce each other’s perceptions and feelings. Once this starts, the perceptions and feelings that they both share an interest in each other will grow stronger.

Thus, as soon as two agents begin sensing that they both share a common interest in each other, a relationship begins. The relationship continues to develop for as long as their interests are aligned. In other words, it is the reinforcement of each other’s perceptions and feelings that makes the experience of the relationship real to them. Becoming aware of another person’s interest in us, when it is a shared attraction, strengthens the relationship experience. This is how second-person perception emerges.

This process does not work when we are attracted to someone who feels indifferent to us. There is no reinforcement of perceptions about a mutual interest, so the relationship never becomes real. This process of coupling with another is a powerful experience. Perceptions and feelings of an emerging relationship stand out as special and distinct from any other type of experience, further strengthening the relationship. In other words, the inner dynamic of second-person relationships are driven by a process of positive feedback.

The moment we, as human beings, see and feel a distinction between self and others, we not only reinforce the experience of our self, we can also, at the same time – whether we realize it or not – sense others as “you.” If this is what happens at the human level, the same process needs to happen at the quantum level. This means that quanta are drawn to form relationships with other quanta when the interest is shared and mutual. The relationship then takes on a life and reality of its own. This process of perception is so dynamic that it feels alive. This is what makes relationships special and why they lead into dramatically new types of experiences.

This process of positive feedback also happens unconsciously. Simply being with someone can trigger a desire to know them better. We call it “chemistry.” According to this postulate, this sense of attraction also happens between quanta. We will see later that there is strong physical evidence that this is true. In fact, this attraction is the origin of the forces of physics. And mutual feelings of repulsion can emerge in the same way.

This means that both first-person and second-person perceptions grow from the difference between self and others. However, while both of these lenses of perception are sparked by the experience of otherness, they follow different paths. First-person perceptions heighten the distinctions we notice, making the differences sharper and clearer as they evolve. Relationships, on the other hand, grow into shared experiences.

From this postulate we can make an assertion: **A second-person relationship only forms when it is mutually reinforced by another sentient agent.** This means that the inner dynamics of relationships only activate when both agents reinforce each other’s perceptions and feelings of the relationship. If one entity is an inert hunk of matter, like a rock, our first-person perceptions of the rock can grow because we like the beauty and color of the rock, but no second-person relationship can develop because the rock cannot return an interest in us. It never becomes a shared experience.

A second assertion: **Second-person relationships do not switch on or off instantaneously by themselves; they start from mere possibilities and continue to thrive and grow through possibilities.** We call them “possibilities” because they only become real when both agents reinforce them. Therefore, “potentia,” as Heisenberg calls it, acts as “a strange kind of physical reality just in the middle between possibility and reality.” This is why coherent quantum states are never definitive states.

Relationship possibilities continually evolve because perceptions and feelings continue to change. Relationships unfold. They are never certain. And a relationship starts dying when the shared interest flags. Thus, the inner dynamics of relationships are sustained by a shared interest.

From this, I can state the first postulate that directly applies to QM:

4.6 Postulate 6: Quantum Wave Functions Are the Back-and-Forth Reinforcement of Perceptions in Second-Person Relationships

Remember, at this point, there are still no third-person perceptions. No outside observations exist yet. The back-and-forth reinforcement of relationships is only experienced by the sentient agents involved. Second-person experiences stand out because of the highly dynamic nature of positive feedback. Outsiders can never perceive or feel what those involved in relationships experience – the feelings that are mutually reinforced and shared – because these inner dynamics are private and only exist between them. This is what makes the relationship special and real to them.

This explains why outsiders cannot detect quantum wave functions directly. Wave functions never exist as a part of the third-person world that we see outside of us. This goes to the heart of why QM is so difficult to understand when using only third-person lenses.

And from this we can make another assertion: **When physicists say that they are describing the wave function of a particle, they are wrong. Quantum wave functions only describe the inner dynamics of relationships. A particle has no wave function of its own. It is only involved in wave functions through relationships with other sentient agents.** This is consistent with Rovelli's statement that all quantum states and measured values of quantum states are relational.

Note: When physicists talk about the wave function of an electron, this is really describing the relationship between the internal agency of the electron and the electron particle field. This is a different type of relationship, as we will see later.

Another assertion: **Second-person relationships are the source of quantum entanglement.** This is easy to see because entanglement is nothing more than a shared quantum state, such as a shared spin state. Therefore, we can also assert that: **Entanglement is only possible between sentient agents.** Rocks cannot become entangled to each other, but living creatures can, and so can quanta.

Quantum states describe nothing more than the inner dynamics of second-person relationships. The possibilities in those relationships – what they can become – are the dynamics that drive them. These act as superpositions, and now we can see why, because: **the possibilities of what "might" happen next in a relationship do in fact influence what "will" happen next.** The influence of these possibilities is what makes quantum states so fundamental to everything that happens. This leads to an important insight:

For hundreds of years science has been teaching us the lesson of seeing things as they are. We should not let ourselves be fooled by imagination or beliefs. We need to verify and run tests to know the world as it is. This is a lesson learned from third-person perception and classical physics.

The importance of this approach has proven itself over and over in science and technology. Unfortunately, it hits a wall when trying to study living things because how we see and treat creatures affects how they respond. In other words, third-person perception is exactly the wrong lens for studying relationships.

Think about it: In a relationship, is it best to accept the way things are? Should we only try to see the relationship as it is currently? Or, should we actively engage with our partner in sparking the relationship to grow into something more? This is why, when we see and feel new possibilities, we breathe life into relationships. They take on a life of their own when we care and nourish them, the same way we water plants. We do that by seeing possibilities in our relationships. Friendships and families need to evolve, or they fade away.

This is what quantum mechanics is trying to teach us: **Perception – the way we see other living things – is creative because it changes our relationships.** Seeing things only as they are is death for relationships. It stops the process of positive feedback because the possibilities stop evolving. They can never grow strong enough to cross over and become objectively real. (More on this later).

Therefore, if this postulate is right and quantum states are wave functions, which are actually just the reinforced possibilities in relationships, then we can see why they will never obey the Principle of Non-contradiction (PNC) or the Law of the Excluded Middle (LEM), which are two first principles of logic that have formerly been considered self-evident. The paper on "Taking Heisenberg's Potentia Seriously" puts it this way:

> Together, PNC and LEM constitute a principle of exclusive disjunction of contradictories, wherein a proposition P is necessarily either true or false, with no 'middle' alternative. Russell presented LEM this way: "Everything must either be or not be" (Russell, 1912, 113). When interpreted classically, Russell's formulation implicitly only acknowledges one mode of 'being' – that which is actual. Thus, a tacit classical assumption behind LEM is that of actualism: the doctrine that only actual things exist. However, as will be demonstrated presently, in the context of quantum mechanics, PNC and LEM together evince the ontological significance of *both* actuality and potentiality, given that every quantum measurement entails the former's evolution from the latter by way of probabilities, which also satisfy both PNC and LEM. (Kastner, Kauffman, and Epperson, 2017, pp. 5-6)

In other words, quantum formalism is showing us that possibilities determine the probabilities of what will become actual. If quantum states by themselves are not actualities, but relationship possibilities, it is easy to see that they will still have a very real impact on sentient agents. They will play important roles in physics because relationship possibilities are highly dynamic in shaping everything that actually happens. However, they do not obey the laws of actual realities.

We should also remember that, beneath the surface of all relationships and wave-functions, first-person perceptions are always present and active. Yes, sentient agents reinforce each other's perceptions in a thriving relationship. But shared interests must arise from the interests of each sentient agent. This is why the behavior of quanta is unpredictable. Relationships shape everything that happens in the world, but they lead only to statistical laws because relationships ultimately depend on first-person perceptions as well. How two sentient agents respond to each other cannot be predicted, even by the partners themselves.

However, the quality of spontaneous and fluid aliveness that we see in relationships seems to be missing in the classical world of rocks, mountains, and planets. Inert "things" do obey the laws of PNC and LEM. Why do the creative powers of possibilities disappear in the classical world? From the principles described above, we now have the tools to start answering this question.

4.7 Postulate 7: Third-Person Perception Emerges from Experiences with Third-Person Relationships

We are on a journey to see how everything emerged from nothing but consciousness. How far have we come so far? We have agents with first-person perception, and we have a world filled with second-person relationships. In other words, we are still a lot closer to "nothing" than "everything." The tangible world does not exist yet. There is no matter or energy, and we have yet to see anything close to Newton or Einstein's idea of space.

However, there is a perception of time at this early stage: the experience of time flowing that comes from evolving relationships. Gradual growth in the back-and-forth reinforcements of perceptions, as relationships unfold, create the perception of time passing, but this is only experienced by agents in relationships. A recent quantum experiment validates that this is indeed a source of local time:

> Time is an emergent phenomenon that is a side effect of quantum entanglement, say physicists. And they have the first experimental results to prove it….
>
> [T]hey confirm that time is indeed an emergent phenomenon for 'internal' observers but absent for external ones. (The Physics arXiv Blog, 2013)

In other words: **Second-person perception leads to a relational experience of time that flows and varies with the intensity of the relationship.** Thus, time speeds by when we are having fun.

There is also a sense of space that exists in relationships. I call it relational space. For example, we feel a sense of closeness in relationships that reflects our level of interest and our involvement. However, this is nothing like the kind of third-person space that we experience in the world outside of us. Third-person space is a universal public space, you might say, not a private relational space that can only be perceived by those involved.

Fortunately, a sense of three-dimensional space began emerging as soon as the first third-person relationships started. And we now have the principles to see how this began.

If we go back to a point where the world had only two sentient agents, we find only first-person and second-person experiences and perceptions. However, as soon as more agents arrive, the story changes. Most of these agents form one-on-one relationships with each other. As a result, new perceptions start emerging that make all of these relationships more complex.

To illustrate, imagine transferring to a new university. You start making friends as you get to know people. After forming a few personal friendships, you notice that your new friends have friendships of their own with others. How do you feel about their friendships? What if some of their friendships are with people you do not like? Think of how it feels when your friend's other friendships seem stronger than the one you have with your friend? You notice these things, right? Why? Because these are outside influences that affect your relationship with your friend.

All of your friend's friendships have an influence on your friend. Those relational possibilities all affect your friend at the same time. In other words, they act the same as superpositions because this is where superpositions come from. So, when you become entangled with a friend, you also become entangled with your friend's friends, but this is a different type of entanglement.

I call these "third-person relationships." They are different from personal one-on-one relationships that you have with your friends. For example, you may know the names of your friend's friends and something about them, but you do not really know them. You know *of* them. If you meet a friend when they are having lunch with their friends, it can feel a bit weird at first, as if you are on the outside looking in. You see something going on between your friend and his or her friends that you are not involved in, except you *are* involved in a strange way through your friend.

In other words, third-person friends seem impersonal. They also act as outside influences affecting your second-person relationships. You notice things about them when you first meet them, such as how tall they are, the color of their hair, or the clothes they are wearing. These are the same types of first-person perceptions you would have when meeting a stranger, because they actually are strangers to you, until you get to know them better. You may feel entangled with them in a strange way, because they are your friend's friends, but relationships with your friend's friends feel far less personal and they seem more like outsiders to you. They only interest you because of the way they affect the second-person relationship that you have with your friend. This is the nature of third-person entanglement.

How does third-person entanglement work? We know that second-person relationships develop through dynamic back-and-forth exchanges that evolve through the reinforcement of two people's interest in each other. Second-person relationships take on a life of their own – a life that is shared only between the two involved. They are highly dynamic because of positive feedback that evolves and grows. The possibilities in second person relationships are the foundations of quantum states.

Third-person relationships, on the other hand, are quite different because there is no reciprocal positive reinforcement of possibilities. This is why third-person relationships feel impersonal. And yet we are still entangled with our friend's friends because they are entangled with our friend. In other words, third-person entanglement only exists because of second-person relationships.

Our lives are clearly expanded by our friendships. We meet countless people through our friends. Those third-person friends also have friends. And, of course our friends have families and their friends have families. And the members of our family, with whom we grew up, also have friends who have friends. We are in a strange way related to almost everyone in the world through friendships or families. Whether there are no more than six degrees of separation between us and anyone else, as one author suggested, the fact is that we are all entangled in a strange indirect way.

Why is this important? Because, as Wigner said, we listen to our friends, and because of that we also listen to our friend's friends as well. They become sources of information for us. We may not trust people we do not know, but when we hear information over and over from many third-person friends, the information compounds to take on a sense of reality.

This directly relates to the story I told in section 2.1.1, where you go to a party and a fight breaks out. You learn about what happened from the third-person perceptions of others. Now we can see what was happening: Third-person information comes to us through our friendships. This is why the relationship you have with a person passing information to you determines how much weight you give to the things they say. And, since everyone at the party is related through friendships to everyone else who is there, you listen at least partially to what everyone says.

The stories we hear become clear only when a consensus emerges about what happened. In other words, the third-person stories need to agree with each other. Only when a clear consensus emerges about what happened, such as where the fight happened and who was involved, will we have a solid feeling that the story is telling us something that really did happen. We gain this solid feeling not just because we feel the weight of agreement between all the stories, but also because everyone else feels this weight as well.

In other words, when stories agree with each other, those stories take on a sense of objective reality. When stories do not agree, they seem weak – not real. This is distinctly different from the reinforcement of feelings and perceptions in second-person relationships that grow from the one-on-one, back-and-forth exchanges between two people, making their relationship a private affair. With third-person relationships, it is third-person (outsider) stories that seem real when they agree.

This process is actually based on negative feedback, not on the positive feedback we see in second-person relationships that makes them so dynamic. Negative feedback is the way oscillating systems converge. For example, negative feedback shuts off the heater in your house when your house reaches the threshold temperature on your thermostat. Third-person stories converge for the same reason. History books are great examples of third-person stories converging from thousands of people. However, only the outsider stories converge. The personal experiences of people who lived during the same period of time vary so widely, from person to person, that they do not converge.

With second-person relationships, we see positive feedback creating relationships that have a life of their own. It is positive feedback that makes them dynamic. Third-person perceptions, on the other hand, reach consensus only when they agree. Differences weaken third-person stories. On the other hand, differences in second-person relationships often make things more interesting.

Therefore, third-person perceptions converge through a form of negative feedback from everyone, creating a consensus view. This is how our experience of a public reality emerges.

The third-person world – the world "out there" – is created by outsider perceptions that agree. Third-person relationships are also where "outside" forces come from.

Let's translate this back to the quantum world. The key elements are:

1. Second-person relationships, in a world of sentient agents, leads to outsider experiences. When it comes to relationships with third-person "friends," every agent is on the outside. These third-person relationships form only through second-person relationships.

2. Third-person relationships are sources of outsider perceptions. Third-person relationships also act as outside forces that influence personal relationship possibilities (quantum states).

3. When outsider perceptions agree from many sources, the consensus converges – producing a public reality. These perceptions consolidate through negative feedback, creating a norm. At the same time, differences in third-person perceptions fade away through negative feedback because they do not seem real. This creates an outside reality perceived by all of the agents related through third-person relationships.

4. **This third-person outside reality is what physicists call a "field."**

5. At the human level, fields are called "societies" or "communities." It is easy to see, at the human level, that these perceptual fields are formed by the perceptions of the people.

6. Most physicists think of fields as the driving sources of change in our world, with particles being merely the ripples on those fields. It is easy to see why third-person relationships act as if they are external forces, however, the LoP Interpretation says that sentient agents are the true source. Their outsider perceptions create and sustain all fields. It is easier to see this at the level of living creatures, but it is just as true for quanta.

I will now state this as a postulate and describe the results in detail:

4.8 Postulate 8: Fields Are Created by Third-Person Relationships

With this statement, we enter uncharted territory. This postulate tells us that fields are created by a special type of relationship. This is a different type of entanglement than the type seen in personal second-person relationships. And the results are dramatically different.

For example, second-person relationships are intense and highly personal. The inner dynamics are only experienced by those who are directly involved.

Third-person relationships, on the other hand, are impersonal. This is why third-person perceptions form the background of the world, not the dynamic foreground. Also, fields emerge unconsciously through negative feedback. This is why they seem automatic, not personal or dynamic.

A tapestry of third-person relationships creates our public reality. It is reinforced by everyone. This process of reinforcement spreads so far out across our web of relationships, and is reinforced by everyone so unconsciously, that the public reality seems to exist on its own. It seems to be a reality that is not altered by how we see it, because our individual perceptions are just one out of millions. However, the “real world out there” is simply a consensus of everyone’s third-person perceptions.

We hardly notice the subtle ways that we accept and adjust to the social culture we live in until we visit a foreign land. Then the differences jump out at us. Social influences coerce us to go along with the crowd, even though people rarely force us overtly. Peer pressure is usually an impersonal pressure that seems to come from everyone. It pushes us all to conform. This is how fields act as external forces.

This postulate leads to a number of significant insights. However, no other interpretations of QM suggest that there are different types of entanglement, as far as I know. This means that this postulate faces a major challenge. We need to confirm that it is valid.

Fortunately, this postulate solves one of the biggest problems in the interpretation of QM: how quantum states create a macroscopic world that seems solid and objectively real.

> *The classical limit of quantum mechanics* refers to the belief that quantum mechanics is a more fundamental theory than classical mechanics, so that classical mechanics should emerge from quantum mechanics in some appropriate limit.
>
> Ideally, this emergence would result from some simple limiting procedure.... Alas, no generally applicable route to the classical limit has ever been found. Despite what some textbooks suggest, it is not clear how, or even if, the classical limit can be realized. It now appears that any resolution of the classical limit problem will require, at the least,

> *both* a limiting procedure *and* accounting for the interaction of quantum systems with the environment through a sophisticated approach known as *decoherence.* (Bowman, 2008, p. 31)

Third-person relationships offer a solution to this problem. Negative feedback creates the limiting procedure that has been missing because third-person perceptions converge when they align with the consensus. This is how the classical reality of an external world with external forces emerges. Societies and fields seem to exist on their own. They do not seem to be affected by how we see them because they are formed by countless outsider perceptions.

The process that forms fields and societies is a limiting procedure that creates a classical world for two reasons: First, the effect is weak when only a few sentient agents are involved in third-person relationships. The influence becomes significant only when the group grows large. This is why peer pressure is only noticeable in large groups. Small groups are far more influenced by personal second-person relationships because the effects of fields are small. Second, fields act as forces that resist change. In other words, they create stasis and conformity by converging toward a norm.

These two traits form a limiting process that creates the classical world at the macroscopic level.

This process is also consistent with the approach known as decoherence because the information that converges comes through entanglement with other particles in the environment. However, this new postulate needs testing, because, while the mathematical equations that model the process of decoherence are consistent with fields forming through third-person perception, the interpretation of how this works is quite different from the current theory of decoherence.

4.8.1 A New Interpretation for Decoherence

Since Newton's time, physicists have followed certain beliefs. For example, when an object is measured, and everyone finds the same results, this indicates that we have learned something about the object itself. And, if we want accurate measurements, we need to limit the interference of outside noise. In other words, isolating an object from the rest of the world is the best way to learn about an object's true properties and its state.

Physicists now know that this is impossible for quantum mechanics (Schlosshauer, 2008, pp. 1-3). Tangible and visible objects are always coupled (entangled) with the environment. The moment we make a measurement, we couple with the object being tested along with our equipment. More importantly, the process of entanglement, according to decoherence theory, is what appears to cause the “classical” tangible world to emerge from pure quantum coherent states.

> [O]ver the past three or so decades it has been slowly realized that the isolated-system assumption...had in fact been the crucial obstacle to an understanding of the quantum-to-classical transition. It was recognized that the openness of quantum systems, i.e., their interaction with the environment, is *essential* to explaining how quantum systems...become effectively classical: How their “quantumness” seems to slip out of view as we go to larger scales. (Schlosshauer 2008, pp. 3-4)

Decoherence theory says that the wave-like nature of quantum states spreads out and couples with the environment. This means that entanglement is ubiquitous. Classical objects, such as rocks and trees, appear to exist in specific places only because the particles are entangled with the world.

This is why, after a photon in a two-slit experiment becomes entangled with the environment, the interference pattern disappears, because the environment then learns information about which slit the photon goes through. When the path of the particle is not known by the environment, then each slit represents a possible path that the photon may take, and the possibilities of these two paths interfere with each other because they act as superpositions.

The theory of decoherence says that particles lose their "quantumness" when their superpositions "leak out" into the environment through entanglement. Do not worry if all of this seems difficult to picture. A number of physicists have problems with this explanation as well. And this theory does not agree with the LoP Interpretation. To understand this better, we need to take a closer look.

There are a few important facts that make decoherence easier to understand. (The following are from Schlosshauer, 2008). First, we need to know that there are degrees of entanglement:

> This raises the question of how to quantify entanglement, i.e., of how to measure "how much" a given state is entangled. This question is important to decoherence. As we shall see, broadly speaking, the higher the degree of entanglement between the system of interest and its environment, typically the stronger will be the decohering effect of the environment. (p. 32)

The key to measuring how much a given state is entangled comes down to this: If you measure one particle, and this measurement tells you a lot about the state of its entangled partner, then they are strongly entangled. For example, if you measure two entangled electrons and you learn that the spin of one is "up," and this tells you that the spin of the other electron is "down," then these two electrons are "maximally" entangled (pp. 32-33). Full entanglement like this means that you know everything about the spin state of the second electron by measuring the first electron.

On the other hand, if you measure the momentum of one electron and it only vaguely tells you anything about the momentum of the second electron, then the entanglement is weak. If it tells you nothing at all about the momentum of the second electron, then there is no entanglement of the momentum state at all.

The next thing to know is what defines how much entanglement is possible: The degree of possible entanglement is determined by how distinct the quantum states are in relation to each other. For example, in the case of spin, there are only two possible states when they are measured: "up" or "down." And entangled electrons must always be in opposite states when they are entangled. Thus, their spin states are perfectly distinct in relation to each other: They always have exactly opposite spin states. If the spin state of one is "up," the other must be "down."

The momentum of free electrons, on the other hand, can vary across wide ranges of speeds and directions, making it difficult to entangle momentum states because the differences are not black and white, but various shades of grey. (Momentum states of electrons in atoms are different; they are distinct. This, in fact, is usually how maximally entangled electrons are created. They come from electrons that share the same shell in atoms). This leads to an important conclusion: "[T]his distinguishability of the states of one system correlated with the states of another system lies at the heart of an understanding of the conceptual basis of decoherence" (p. 33).

In other words, entanglement needs distinctions. This is why distinguishability is a defining factor. This perfectly aligns with the principle of perception I outlined in section 4.3: **Perception begins with the sensing of differences.** Thus, distinguishability is the foundation of perception itself. And, remember, perceptions must be reinforced for entanglement to form. Therefore, the fact that distinguishability defines the strength of entanglement makes sense because distinguishability defines the strength of perceptions. Postulate three explains why entanglement works this way.

Now, based on what Schlosshauer says above, the current theory of decoherence then states (I will explain what the quote below means afterward) that information about a system being tested, such as a photon in a two-slit experiment, spreads out into the environment through entanglement, and the amount of information that spreads

> increases with the amount of system-environment entanglement, and thus also with the distinguishability of the relative states of the environment correlated with the different component states of the system. The larger the amount of this information about the system learned by the environment becomes, the more the system loses its individuality (in the sense of the inability to assign an individual quantum state to it). As a consequence, quantum coherence initially localized within the system will become a "shared property" of the composite system-environment state and can no longer be observed at the level of the system, leading to decoherence. (p. 33)
>
> Some states of the system are more prone to decoherence than others, and the sensitivity of a particular state is determined by the structure of the system-environment interaction. The preferred states of the system emerge dynamically as those states that are the least sensitive, or the most robust, to the interaction with the environment, in the sense that they become least entangled with the environment in the course of the evolution and are thus most immune to decoherence…. Similarly, we may say that the interaction with the environment "superselects" the observable states of the system: Some states are robust in spite of the environmental interaction, while other states are rapidly decohered and become therefore unobservable in practice. (p. 73)

The above three paragraphs are the best and clearest explanations I have seen in all the papers and books on decoherence that I have read. However, the details of how the classical world is supposed to emerge, according to this theory of decoherence, are still incredibly vague. Especially, the story about how the "preferred states" of a system emerge through a process that sounds a lot like a happenstance of interactions between the system and the environment.

I will get into more about preferred states later. For now, I want to show the problems in the above three paragraphs, in relation to the LoP postulates of perception.

First, saying that the system being tested loses its individuality when it becomes entangled with the environment is problematic. The first paragraph says that this refers to the quantum state of the system. Thus, the quantum state supposedly loses its individuality. The problem is that this treats a quantum state as if it is a thing. Third-person lenses would certainly like to see it this way, but if the LoP Interpretation is right, quantum states are possibilities in relationships, not things. Clearly, it does not make sense to say that a possibility in a relationship loses its individuality.

It also makes no sense to say that sentient agents lose their individuality when they become entangled because it is not even possible to become entangled unless they are different. Remember, distinguishability is the crucial factor in determining how strongly they become entangled. If this is true, then how can entanglement with the environment cause a loss of individuality? It cannot. The distinctiveness between one agent and another is why they become entangled in the first place.

This brings us to the second issue. According to the postulates I have outlined above, only sentient agents can become entangled. This constraint means that the environment cannot form entangled relationships. Rocks cannot become entangled either. Only sentient agents can couple.

This raises a question: How do we know which agents belong to the environment and which belong to the system being tested? In the case of the two-slit experiment, it is easy, because the photon is the system and everything else is the environment. However, it is not easy to draw this line when it comes to living organisms because they are continually making exchanges, back-and-forth, with their habitat. In fact, I question whether it is even possible to draw a line that separates any system from its environment, especially when we are talking about quantum states that are relationships themselves. For example, a simple electron gains its mass and spin characteristics from its relationship to the electron particle field. If this is true, then how can an electron exist separate from that field?

As soon as we look at entanglement through the LoP lens, a third, bigger problem becomes clear: One-on-one entanglement between sentient agents does not create a shared "system-environment state." It creates private one-on-one relationships. For the environment to form a shared state, third-person entanglement is necessary. However, third-person entanglement does not share the inner dynamics of private one-on-one relationships. This means that superpositions do not leak out from private relationships when particles become entangled to other particles in the environment. Only third-person outsider perceptions spread out. Second-person superpositions remain private.

As a result, the quantum coherence (or quantumness) of a quantum state is not leaked out into the environment when sentient agents become entangled with other agents. The only things that spread throughout the environment are third-person perceptions. This is easier to see with living creatures because they breathe in air molecules made by other organisms and breath out molecules that other organisms need. Losing their shared quantum state would mean death. So the idea that decoherence causes objects to become separate and independent from each other is a problem.

The second paragraph above is even more problematic. It says that some states of the system are more prone to decoherence, and the factor that makes a state more sensitive to decoherence is determined by the structure of the "system-environment interaction." This is quite vague. It then goes on to say that the "preferred states" of the system, which are the states that most clearly stand out to define how we see that system, emerge because they avoid becoming entangled with the environment. This is seriously mixed up, according to the LoP Interpretation.

First, there is no mystery about which states decohere and which do not, according to LoP. Only third-person perceptions decohere. This is what spreads throughout the environment. Consensus forms to create one public consolidated picture. When we measure a system, this third-person information is what we are gathering. We are not seeing "preferred states" of the system itself. We are seeing the public consensus of third-person information about the system. This is why a rock appears to be located in a certain place on the ground, and it looks the same way from all viewpoints. Everyone sees the same outer reality because these are third-person perceptions. We are not looking at the state of the rock. We are looking at the shared outsider picture of the rock. That is what we see with our eyes and instruments, making it look like an external reality.

The same thing happens at the human level. For example, consider people calling someone "a movie star." Star status is not a property that belongs to them by themselves. That is a consensus perspective seen by people in society. When a person becomes famous after playing major roles in a number of successful movies, we feel comfortable saying that it is a fact they are a movie star. However, star status is not clear if an actor has only a minor part in one movie. Their status as a star is then debatable. There is no consensus. Thus, the state of being seen as a movie star emerges as they play major roles in more movies. Therefore, according to the LoP Interpretation, "preferred states" emerge through a simple process: the consensus that forms from third-person perceptions.

The third paragraph, in the quote above, turns this issue into an even bigger problem by suggesting that the environment "superselects" the preferred states. This process, called "einselection" (short for environmentally-induced selection), is often compared to Darwin's theory of natural selection, where the environment selects the fittest creatures by killing off those that are least fit. There are two big problems with this comparison to natural selection. First, evolutionary fitness is nothing more than the ability of a creature to survive. This means that the whole concept of fitness is circular because a creature's survival is also how we measure its fitness.

Second, Darwin's theory is about the survival of living creatures. We do not see rocks or piles of sand evolving. More importantly, Darwin knew that lifeless properties in an environment, such as temperature or wind, only cause creatures to adapt to changes in the environment. No new species or abilities "emerge" through natural selection this way. The emergence of new abilities and new species requires life responding to life, such as through competition, where predators hunt for prey, or symbiotic cooperation between life forms. The reason Darwin said this is because dynamic, positive feedback is needed to create the directional power of evolution. Thus, the real driver of evolution is the relationships between sentient agents, bringing us back to the LoP Interpretation.

> Natural Selection, at the "bare bones" of its mechanism, only builds adaptation to changing local environments; the principle includes no statement about inherent directionality of any kind, not to mention progress.
>
> Darwin resolved this…by invoking a particular ecological context as the normal stage for natural selection. If most ecosystems are chock full of life, and if selection usually operates in a regime of biotic competition [living organisms competing with other living

> organisms], then the constant removal of inferior by superior forms will impart a progressive direction to evolutionary change in the long run. (Gould, 2002, p. 479)

Once we bring the discussion back to the relationships between sentient agents (the LoP theory), the picture becomes clearer. The dynamics driving the quantum-to-classical transition are based on the spreading and consolidation of third-person perceptions across a web of third-person relationships. This is how our experience of the world out there is created. On the other hand, the processes that create new species and new abilities depend on personal relationships between sentient agents.

Of course, it does *seem* as if the environment is selecting. The public can *seem* quite fickle in its love of movie stars. Harsh environments at work do *seem* to decide the fates of creatures. However, when we look at this from the quantum level, from the level of sentient agents, it becomes clear that sentience is needed to make true choices – to do any selecting. People choose, not the public.

With the above explanation, we can now compare decoherence theory against LoP theory. Let’s take a look.

4.8.1.1 The Speed of Decoherence

We need to separate this discussion on decoherence into two parts. First, is the mathematical description of how interference patterns disappear as particles like electrons and photons interact with other particles in the environment. Second, we need to compare the interpretations about how this process works and what it means.

Starting with the first part, mathematical equations have been developed to predict the speed of decoherence. These equations have been validated by experiments. Countless tests have shown that the more interactions a particle has with other particles when passing through a two-slit experiment, the more rapidly the interference pattern disappears.

Interactions with the environment do not have to involve transactions of energy; they can be purely quantum interactions that arise from passing by or being close to one another. However, in most cases, energetic interactions are also involved, such as interactions with air molecules, photons from ambient light, background radioactivity, cosmic radiation, solar neutrinos, etc. (Schlosshauer 2008, p. 115). Very little interaction is needed to create a measurable amount of decoherence.

A full mathematical analysis of the equations that have been shown to predict the disappearance of interference patterns is quite complex and beyond the scope of this paper. However, the main factors driving those equations are based on the principles I described above, along with a couple additional factors. Let’s review them one by one.

1. The degree of entanglement is an important factor, as I said above. According to decoherence theory, this is determined by distinguishability.

   The LoP Interpretation agrees. Distinguishability determines the strength of entanglement because distinguishability determines the strength of perception, and perception must be reinforced for entanglement to exist.

2. According to decoherence theory, the higher the degree of entanglement, the stronger the decohering effect will be.

   The LoP Interpretation places an equal weight on the importance of entanglement. The stronger the entanglement (meaning second-person relationships), the more it becomes a channel for information to flow out to other sentient agents in the environment, and for information to flow from the environment to the system being tested. Strong second-person entanglement increases the decohering effect because information carries more weight when coming from a trusted source (with a higher degree of entanglement). This is easy to understand at the human level. However, the LoP Interpretation says that it is third-person relationships that pass along the outsider information that provides the decohering effect. Nonetheless, the mathematical weight from second-person entanglement will be the same because all third-person relationships come through second-person relationships.

3. If the strength of entanglement is a factor in decoherence, then distinguishability plays a crucial role in deciding which quantum states will decohere the fastest, according to the theory of decoherence. This means that position and momentum states, which differ only in grey variations, not black-and-white distinctions, will not spread across the environment, but will remain behind as “preferred states” of the system being tested. Distinctly defined states (such as the two-slit options) will lose their superpositions as those superpositions spread out into the environment. For the same reason, it will not be easy to assign an individual quantum state to spin states, because they are also distinctly defined.

   The LoP Interpretation says that this is backwards, but the end result is the same. Position and momentum information is what spreads throughout the environment because this is third-person information. This is why the first information to decohere is the position and momentum of a system. If an electron does not interact with other sentient agents, there is no way of knowing where the electron is located or what its momentum is. However, when location information does spread, it suppresses the interference patterns in two-slit experiments because the path of the photon becomes publicly known. (More on this later).

   Entangled spin states are different. They are not weakened by third-person information because their shared spin state is the result of a second-person relationship. This is why entanglement between photons has been shown to persist when separated by more than a thousand miles, even when the photons go through fiber optic cables, bounce off mirrors, and pass through optical beam-splitters and prisms. This is why entangled spin-states are notorious for resisting decoherence.

4. The most important factor for defining the speed of decoherence, according to the theory of decoherence, is the number of particles that the system being tested becomes entangled with, and the number of other particles that those particles become entangled with.

   LoP theory agrees, because it is those “other particles” that receive and pass along third-person information, and each particle that becomes directly entangled with the system being tested opens up new channels of information that flow out to those “other particles.” The total number of particles involved play a defining factor because the more that third-person information is confirmed by others, the more influential it becomes. At the human level, this is easily seen by how peer pressure and the need to conform increases as the size of a company grows. Small start-up businesses experience far more freedom and spontaneity, while large institutions become strapped by red-tape and bureaucracy. This all happens so unconsciously that it seems mechanical and external.

5. The size of the system being tested can also be a factor, according to decoherence theory, because the larger the system is, the more likely it will interact with particles passing by.

   LoP theory agrees with this for the same reason.

These are the factors that have proven successful in predicting the speed with which interference patterns disappear through decoherence. As you can see, decoherence theory and LoP theory agree on the weighting factors determining the rate of decoherence. Perhaps a more detailed analysis can identify differences that are testable. More study is needed to see if that is possible. For now, I see no way to distinguish how these two theories predict the speed of decoherence.

Next, I compare the interpretations. Here there are clear differences that affect the outcome.

4.8.1.2 Interpreting the Process of Decoherence

According to decoherence theory, the process of entanglement causes the quantum coherence of particles to leak out into the environment. The environment effectively absorbs the superpositions that make quantum states so hard to nail down. This causes particles to become “classical” in their behavior. In other words, after decoherence, particles act as if they are located in clear positions, have clear trajectories when they move, and have clear momentum states. As a result, it is common for decoherence theorists to declare that the wave-like nature of coherent particles disappears, and their particle-like nature emerges through decoherence.

Another important claim is that these clearly defined “preferred states” that emerge through decoherence are selected by the environment through a process called “Quantum Darwinism” (Zurek, 2009). Thus, the theory of decoherence is often claimed as a solution to how the quantum world becomes classical.

However, there is a fundamental issue with the above interpretation: It all depends on a distinction between the system and its environment. Without a distinction, there is no entanglement between the system and the environment. And without this entanglement, the distinctiveness of the system cannot emerge. Therefore, the claim that decoherence explains the quantum-to-classical transition also requires the property of distinctiveness, in the beginning, that it claims to produce in the end. This is clearly a problem of circularity. If distinguishability is needed for entanglement to begin, then no one can claim that decoherence creates distinguishable states.

Schlosshauer (2008), quoted above, explains the matter this way:

> Note that decoherence derives from the presupposition of the existence and the possibility of a division of the world into “the system” and “the environment.” (p. 101)

> This system-environment dualism is generally associated with quantum entanglement, which always describes a correlation between parts of the universe…. [T]erms like "observation," "correlation," and "interaction" will naturally make little sense without a division into systems. (p. 102)
>
> However, the assumption of a decomposition of the universe into subsystems (as necessary as it appears to be for the emergence of the measurement problem and for the formulation of the decoherence program) is definitely nontrivial… Zurek was one of the first to clearly point out this conceptual difficulty:
>
> In particular, one issue which has been often taken for granted is looming big, as a foundation of the whole decoherence program. It is the question of what are the "systems" which play such a crucial role in all the discussions of the emergent classicality (…) [A] compelling explanation of what are the systems – how to define them… – would be undoubtedly most useful. (Schlosshauer, pp. 102-103)

In other words, the question is: How do distinctions between systems come into existence in the first place? A reviewer of Schlosshauer's book, N. P. Landsman (2009), is more pointed about this issue:

> [D]espite Schlosshauer's insistence that "the decoherence program is derived solely from the well-confirmed Schrödinger dynamics" and that accordingly this program "attempts to explain the emergence of classicality purely from the formalism of basic quantum mechanics" (p. 337), in actual fact the whole program hinges on an interpretational move that cannot be read off the Schrödinger equation or any other ingredient of the formalism. The move in question is the assumption that…the einselected states form a basis,...this 'preferred' basis is taken to be the one over which the theory is interpreted.... Nothing in the formalism dictates this procedure. (p. 2)

This preferred basis is the set of properties that define the system. According to decoherence theory, this basis is formed by "the structure of the system-environment interaction," as Schlosshauer says above. This is why I said that this process is vague, because it is not defined by quantum formalism. It just somehow works out through happenstance. Other articles suggest that this problem goes much deeper. It is fatally flawed.

For example, Fields (2018) points out that "environmentally-induced superselection," known as einselection, is presented as an "observer-independent mechanism by which apparently classical systems 'emerge'" (p. 1). The assertion that this process is observer-free makes it an attractive idea to physicists because it fits the traditional lens of classical physics. As a result, it appears as if einselection converts the

> environment from a passive sink for quantum coherence into an active "witness" that continuously determines the observable states of the systems embedded in it… Quantum states that are continually "witnessed" by the environment are effectively classical; hence it has been proposed, under the rubric of "quantum Darwinism," that einselection provides an observer-independent physical mechanism for the emergence of classicality… If this proposal is correct, einselection answers one of the deepest questions in quantum measurement theory: the question of "how one can define systems…." In recognition of this, einselection has been called "the most important and powerful idea in quantum theory since entanglement."

> The present paper shows that a recognizably classical world of discrete, bounded objects acted upon by external forces only emerges via einselection if "systems" are defined in an observer-dependent way. It thus shows that einselection does not provide an observer-*independent* mechanism for the emergence of classicality. (p. 2)

Fields goes on to show that for einselection to work, it must first assume that subsystems exist. In other words, "the 'environment as witness' formalism implicitly assumes the effective classicality of the environment" (p. 3). If it has to assume the classical world exists to begin with, in order to make the theory of Quantum Darwinism work, it does not provide a mechanism for the observer-*independent* emergence of classicality. For that emergence claim to be true, according to Fields, "einselection must not only establish a preferred basis for *S* [the system], but also establish a boundary for *S* that separates and hence distinguishes it from all spatially-distinct systems" (pp. 3-4).

This is significant because there is no entanglement possible without this distinction. More importantly, as Fields points out, there is nothing in quantum theory that determines the choice of what the system is and what it is not (p. 6).

In other words, a particle-like property cannot emerge through einselection because the distinction between the system and the environment is needed for entanglement to take place. If only coherent wave-like properties exist to begin with, there are no boundaries, no clear distinctions, because wave functions spread out everywhere. After a lengthy detailed analysis, Fields continues:

> Einselection cannot, therefore, be viewed as an observer-independent mechanism for the emergence of classicality; doing so requires the assumption that the environment is effectively classical and is therefore circular. This circularity cannot be rescued by a bootstrap argument, since an effectively classical environmental fragment must be assumed for every emerging object, and such an assumption must be made independently for every observer. It also cannot be rescued by assuming a physical but observer-independent restriction on the choice of systems to be einselected. Any such restriction…also introduces circularity.... If einselection is to be considered a physical mechanism for the emergence of classicality, therefore, it can only be considered to be an observer-dependent mechanism. (pp. 8-9)

This explains why Bowman (2008) said (above) that decoherence alone cannot explain the emergence of the classical world. A limiting process is also needed (p. 31).

The point that Fields is making here is significant. It not only says that we must give up the idea of observer-independence when it comes to analyzing the processes that lead to decoherence. It also implies that only observer-*dependent* mechanisms are possible.

Even Rovelli, who shows that there are no observer-independent quantum states or values, does not seem to fully recognize what this means. Fields' point tells us that Rovelli's Galilean observer, a lamp, must be abandoned, because the lamp is a classical object. (See section 2.1.2 above).

We cannot start with classical objects. We must start with quantum states. Everything that Fields says here is in agreement with the LoP Interpretation.

The process that leads to entanglement starts with sentient agents perceiving distinctions between themselves. These agents possess clear properties that distinguish them as individuals because of their internal agency – their ability to act in response to perceptions. However, the spatial boundaries of these internal agents are not well-defined in any way because they are entangled with others in their “habitat,” the same way that living organisms cannot be clearly defined without killing them. It is their individuality that is well defined by the way they carry mass and energy, but this only displays itself when they are measured, or when they actively exchange energy.

Fields asks, What are the “fragments” of “every emerging object” that grow to take on the classical properties that we see? The LoP Interpretation can answer this: Sentient agents are the fragments. The classical world emerges through the consensus of third-person perceptions. The environment emerges as a field, establishing an external world that appears to exist independently of observers. This third-person consensus forms the “basis” for how objects are seen. But, none of this is observer-*independent*. In fact, every step in the selection process requires first-person perception because only sentient agents can select, so, of course, it is fully and completely observer-*dependent* by definition.

If we want to explain the process of decoherence, we need to be able to start with the world’s first observers and show how the third-person classical world emerges naturally. This is the only way to solve this problem. Decoherence theory cannot explain how this happens because it assumes an environment that is distinct from subsystems. LoP theory offers a solution. To illustrate how this works in more detail, let’s look at how the three dimensions of space emerge as a field.

4.8.1.3 Decoherence and an Insider’s View of Space

With the emergence of third-person entanglement, outsider information is shared and naturally converges by suppressing information that does not agree with the norm. This naturally reinforces the norm, strengthening our experience of an outer reality. This all happens unconsciously, so even primitive sentient agents should be influenced by the emergence of this outer reality, the same way living organisms are.

To see how this works on the quantum level, let’s go back to the first sentient agents when they started sensing third-person perceptions. I will start with five sentient agents, named *A*, *B*, *C*, *D*, and *E*. Of course, these sentient agents form entangled one-on-one relationships with many, if not all of the other agents. We also know that all these relationships exist at the same time, and the possibilities in the relationships act as superpositions. We can say that all of the possibilities in the relationships that *A* has with other agents represent its full quantum state.

Now, let’s say that *A* forms a second-person relationship with *B*, *C*, and *D*, when agent *E* comes by. We should expect *A* to sense responses from *B*, *C*, and *D* to agent *E*. For example, *B* might have the strongest response because it is closer to *E* than *C* or *D*. Or *C* or *D* might be closer. Whatever the arrangement, a sense of relative closeness should emerge from the differences that *A* senses between the responses of *B*, *C*, and *D* to *E*. Remember, these are all third-person perceptions, which means that they are all based on comparisons between others. And these perceptions come to *A* through its second-person relationships.

Of course, saying that *A* perceives a sense of relative closeness does not mean that agent *A* has a yardstick and measures how close *E* is to *B*, compared to how close *E* is to *C* or *D*. No, these are purely unconscious perceptions – the sense that *B* responds in such a way that it appears to be nearer to *E*, and that *D* is farther away, you might say. No analysis is involved. *B* simply seems closer to *E* than *C* or *D*, based on their responses to *E*.

These are relative comparisons that *A* senses. This is why they are grey. The distinctions are weak and not at all certain to *A*. Further, these differences only have meaning as comparisons: *B* seems nearer to *E* than the others. The perceptions that *A* has about this are impersonal because they come from the responses of *B*, *C*, and *D* to *E*. And from this third-person information, *A* forms a vague perception that one sentient agent, *E*, is responsible for all of these responses from *B*, *C*, and *D*, because they all seem to happen as *E* passes by. As a result, *A* gains a half-formed perception of a comparative arrangement between the other agents in relation to *E*. This shows why third-person perceptions are different. They do not act as superpositions because they use only negative feedback, not positive feedback, when they combine to form a consensus.

One-on-one personal relationships also exist at the same time, and the possibilities in these relationships do act as superpositions, but they do not combine, because they are privately shared perceptions between agents. This is why second-person possibilities interfere with each other when the phases of their wave functions conflict. The math that describes how this works in quantum formalism is based on treating quantum states not as “real” functions but as “complex” functions, meaning that one of its mathematical axes is located in an imaginary ($\sqrt{-1}$) domain. According to the LoP Interpretation, this imaginary domain represents the private one-on-one relationship state.

Third-person perceptions are different. They are impersonal. As a result, they have no axis centered in an imaginary domain. At first, there is no shared basis for third-person perceptions, but because they relate to things that exist and persist as real (not complex) functions, they naturally converge to form a common basis, creating a field. This is how third-person possibilities converge through consensus. This background reference becomes the basis that all measurements are made from.

If *E* is really there and is passing by gradually, then perceptions of *E* will continue. These will reinforce the perceptions that *E* is there. This will also reinforce *A*’s perceptions that all of these responses of *B*, *C*, and *D* are related to *E*. This strengthens *A*’s half-formed perceptions.

The argument might be raised that there is no way *E* could “pass by” before the field of space exists. This is true, but it is not important because the field of space only emerges from what *is* being perceived and what perceptions *are* persisting. Thus, the perception of *E* passing by emerges.

However, the above discussion is still only about *A*’s perceptions. If third-person information is naturally shared through entangled relationships, as I am describing here, then of course agents *B*, *C*, and *D*, will also gain a sense of *E* from responses of the others, including *A*’s responses to *E*. So, they each develop half-formed perceptions of an arrangement between the other particles through relative comparisons of their nearness to *E*.

When *A*, *B*, *C*, and *D* compare the third-person perceptions of others with their own, which are still only vague perceptions and subtle feelings at best, they will eventually notice that the responses of others seem related to the passing of *E*, but there are differences. They are not exactly the same. When these differences have no pattern to them and no consistency, they will be ignored because they do not appear to represent anything real. Those third-person perceptions perish, you might say. They disappear. However, even subtly agreeing perceptions will be reinforced and gain strength, especially if they persist. Thus, a shared consensus emerges.

It is worth mentioning here that every third-person perception of something real does not need to be strengthened. All that is needed is a general tendency to reinforce perceptions that persist and correlate with other perceptions.

With only five agents in the world, it is hard to imagine any more than a vague sense of an outsider arrangement between the nearness of the agents in relation to each other. However, as the number of agents in the world increases, the experience of a 3-D representation will naturally emerge, creating a spatial sense of a real world. Why three dimensions? Because this experience of an outer reality comes from third-person perceptions that are confirmed by other third-person perceptions.

Let me explain. Every sentient agent is an outsider when comparing others. If agent *A* is only looking at its own third-person perceptions, a two-dimensional map is enough to represent the relative closeness of *B*, *C*, and *D* in relation to *E*. Each comparison can be represented as a simple two-dimensional triangle, with *A* at the apex, and the other two points of the triangle being the two others being compared.

However, the experience of a 3-D spatial reality only emerges when third-person perceptions of everyone converge to form a consensus. This includes other agents' third-person comparisons of *A* to others. This means that every point on every triangle connects to every point on every other triangle. This is why the field of space that emerges is experienced as a three-dimensional reality.

This field of space, however, is not built on a grid of *x*, *y*, *z*, coordinates. It is only composed of consistent relative comparisons of the nearness and movements of sentient agents.

This experience not only creates the experience of an external spatial reality. It also brings to each agent a sense of their own place in that reality. Psychologists call this a "felt sense" of place, and it is well-known that this forms unconsciously (Marman, 2016, pp. 90-96). This experience of being in the world is a big part of what makes our experience of the world objectively real to us. This is one of the results created by third-person entanglement.

If LoP theory is valid, another assertion can be made: **Although the field of space emerges from a consensus of third-person perceptions, there can be no outsider perceptions of the field of space itself.** In other words, any agent who experiences the field of space is involved in that field, and any agent that is not a part of that field will feel no interactions with that field. This means that fields are invisible to outsiders, the same way that second-person relationships are invisible to outsiders, because fields are shared quantum states. Yet, fields have real effects on those involved.

This assertion has important implications, because it solves one of the stumbling blocks that has been getting in the way of developing a theory of quantum gravity. Lee Smolin (2017) explains:

> Among the things we had to struggle with were the implications of the fact that the observer in quantum cosmology is inside the universe. The problem is that in all the usual interpretations of quantum theory the observer is assumed to be outside the system. That cannot be so in cosmology. This is our principle and, as I've emphasized before, this is the whole point. If we do not take it into account, whatever we may do is not relevant to a real theory of cosmology….
>
> What is needed is an interpretation of the states of quantum theory that allows the observer to be part of the quantum system. (pp. 40-42)

This is clearly what postulate 8 accomplishes because it shows that the emergence of space must be *observer-dependent*. However, to see how well the LoP Interpretation fits, listen to how Smolin describes the new understanding of space that has emerged from research into quantum gravity:

> [T]here is no meaning to space that is independent of the relationships among real things in the world. Space is not a stage, which might be either empty or full, onto which things come and go. Space is nothing apart from the things that exist; it is only an aspect of the relationships that hold between things. Space, then, is something like a sentence. It is absurd to talk of a sentence with no words in it. Each sentence has a grammatical structure that is defined by relationships that hold between the words in it, relationships like subject-object or adjective-noun. If we take out all the words we are not left with an empty sentence, we are left with nothing. Moreover, there are many different grammatical structures, catering for different arrangements of words and the various relationships between them. There is no such thing as an absolute sentence structure that holds for all sentences independent of their particular words and meanings.
>
> The geometry of a universe is very like the grammatical structure of a sentence. Just as a sentence has no structure and no existence apart from the relationships between the words, space has no existence apart from the relationships that hold between the things in the universe. If you change a sentence by taking some words out, or changing their order, its grammatical structure changes. Similarly, the geometry of space changes when the things in the universe change their relationships to one another….
>
> The view of space as something that exists independent of any relationships is called the absolute view. It was Newton's view, but it has been definitively repudiated by the experiments that have verified Einstein's theory of general relativity. This has radical implications, which take a lot of thinking to get used to. (pp. 18-19)

The LoP Interpretation takes this further, making it even harder to get our heads around, especially if we are used to the idea of a physical world that only exists “out there.” Postulate 8 is saying that the field of space is intangible to outsiders because it is a quantum state. And the relationships are not formed between “things” or objects, but between sentient agents that are themselves intangible until they exchange energy. This means that there is a difference between the field of space and what physicists call space-time, which I will explain in detail, in section 4.9.

All of this shows the importance of seeing what is happening from an insider’s perspective, not just from an outsider’s point of view. This leads us to another interesting insight: The perception of a sense of place, according to the LoP Interpretation, only exists because sentient agents feel coupled to the field of space. This is similar to becoming the citizen of a country, which is an experience that only exists when we form a relationship with that country as a whole. The society we live in is a field formed by sentient agents, just as the field of space is formed. And to live in a society, we must be entangled in some way with that society. Otherwise, it has no effect on us.

This means that our experience of being here, in a place, is not a complete reality in itself. A sense of place only exists when we *also* have a relationship to the field of space. Therefore, there are two related perceptions that are inseparable: (1) Being in a place in space. (2) Being in a relationship with the whole of space. This is the result of two different lenses of perception.

The first of these two perceptions – a sense of place – comes from a sentient agent's first-person perception. This is their private experience of being "here." And first-person perception, as shown in section 4.5, evolves to make distinctions clearer. This is why our experience of being "here" becomes distinct and real.

On the other hand, our third-person relationship with space creates an experience of momentum. Our feeling of motion comes from being entangled to the whole world out there, not just one location. Therefore, position and momentum are products of two different lenses of perception, but both are related to an agent's experience with the same field of space. This reveals a deep relationship between position and momentum, and this gives us a deeper insight into the Heisenberg uncertainty principle. This is worth a closer look.

4.8.2 The Strange Message of Uncertainty

Measuring an object's position and momentum is not a problem with large objects, such as a car. We can measure its speed and location without noticeably impacting where it is or how fast it is moving. This is why we intuitively picture a car moving across a clearly defined path.

However, when it comes to quanta, everything changes. There is no way of knowing exactly where a particle is going when we measure its location. And if we plot our measurements, we see that the particle follows a fuzzy trajectory. It seems to jump around. Plus, if we measure its momentum, it is not clear exactly where the particle is located. There is an inherent uncertainty that can never be removed, suggesting that quantum mechanics itself is incomplete, as Bowman (2008) explains, because quantum theory states that

> perfectly well-defined values of the electron's position and momentum evidently *exist*: yet there is no experiment by which both can be perfectly *known*…. Taken at face value, then, [this] contradicts completeness, for if the electron's position and momentum are precisely defined, and exist, yet quantum mechanics cannot account for that fact, the theory must be *in*complete. (p. 89)

However, the cause of this issue is not our inability to measure both position and momentum at the same time. The real problem is that position and momentum are related to the same quantum state, and this joint state itself seems to be inherently uncertain for some reason:

> Whether or not simultaneous measurements are in fact possible has been a matter of some debate. Regardless, if one insists on the completeness of quantum mechanics, things become outright weird. If quantum mechanics is complete, then the [quantum] state must fully describe an individual system, say an electron. But all information about the

> electron must be contained in the state, and the state yields "blurry" distributions of x [position] and p_x [momentum]. Thus, the uncertainty relations evidently imply constraints on the *existence* of simultaneously well-defined properties of a single system – that is, not only are the *probability distributions* for x and p_x indistinct, so *are* x *and* p_x *themselves*. Again, this strange result arises from an insistence on the completeness of quantum mechanics. (p. 90)

The LoP Interpretation offers insights into this puzzle. First, we can now see why position and momentum are related: They share one common quantum state – the field of space. Second, this shared position-momentum state *is* blurry because it is nothing but a shared consensus of outsider perceptions. Remember, these are third-person stories. They will never give us a sense of absolute certainty, no matter how many stories agree, because it is all third-hand information.

However, this is not a full explanation. For that we need to include the impact of measurements, which require a wave collapse. In section 4.9.2.8, we will see that measurements disturb the field of space because they represent actual changes in second-person relationships. This is exactly the same point that Smolin (2017) made above when he said "the geometry of space changes when the things in the universe change their relationships to one another" (p. 19). The strange message of uncertainty, therefore, is that the quantum state of space *is* blurry because it is always shifting.

4.8.3 Energy Is Needed to Go Against the Norm

Returning to our previous discussion, if an agent has no experience of being in space, then it has no third-person relationship with that field of space. And, if it forms no third-person relationship with a field, then it feels no third-person ties to other agents in that field. This might seem strange when talking about particles, but we all know people who divorce themselves from their countries and communities, even their families. This shows us that first-person perception is involved in all relationships. Later, we will see why this is important.

Now, as the number of agents in a field grows, the experience of three-dimensional reality grows stronger as a perception. And the stronger this perception grows, the more it influences each of the agents in the field, because they each unconsciously conform to this perception.

What does this pressure to conform feel like? It feels the same way that we as human beings feel when we are in a group and try to go against the norm. It is an unconscious feeling that things will go easier if we go along with others. Why fight against the status quo?

This leads to a significant point: **When the number of agents in a field becomes large, going against the norm takes effort. In other words, real energy is needed.**

This is where it gets interesting. Going against the norm of the field of space does not mean moving from one location to another. It means a change in momentum. We know this from Newton's first law of motion: No force (no effort) is needed to keep an object moving at a steady pace. However, acceleration, which is a change in momentum, does require a force. A force is needed to go against the norm because being tied to a field is what creates inertia. If you push an object that is tied to a field, what happens? You feel resistance. Inertia is this resistance to change; it comes from third-person entanglement to a field.

Think about what this means: The field of space establishes a norm that includes particles staying in one location and particles that are moving steadily, but not particles that accelerate. Accelerating particles are going against the norm. We know this is true because acceleration requires a force, as Newton's second law tells us. Why do fields work this way?

There is a simple reason for this, according to LoP theory. Fields are only created by third-person comparative perceptions that persist. These are impersonal outsider perceptions. All forces, on the other hand, emerge from personal second-person relationships, such as attraction and repulsion. This is why forces disturb fields, creating ripples in those fields. (A detailed explanation for how this works is given in section 4.9). Therefore, we can say that the mass of a particle is created by the strength of that particle's third-person entanglement to a field. This is true because mass is nothing more than resistance to a force. And particles resist forces when they are tied to a field. All electrons have the same mass because they are all tied to the electron particle field.

If a particle belongs to two different fields that are independent of each other, such as the Higgs field and the electron particle field, then that particle will be pulled in different directions, even if the particle appears to be stationary, because the two fields move independent of each other. This is how fundamental particles gain "rest mass."

We experience the same feeling when we belong to two different groups, such as a scientific community and a political party. Each group pulls us in different directions. Thus, politics feels like an outside force to a scientific community.

So, our primordial world has grown. It now includes relational time, three dimensions of space, the need for energy when going against the norm of fields, the emergence of mass and inertia, and the foundation for Newton's laws of motion. Third-person fields bring us a lot closer to the classical world. However, we have not solved the whole puzzle yet because fields are still quantum states. We need space-time events and measurements to fully explain the classical world as we know it.

4.8.4 A New Look at the Two-Slit Experiment

Before we move on, we now have a new way of explaining the two-slit experiment, with what we have just learned about fields.

If there are no other agents nearby, when a photon goes from its source through the slits to a point on the screen, there will be no spatial information about which slit it went through. There is clear spatial information about where the photon hits the screen, and clear spatial information exists for the emitter, because the emitter and screen are both entangled with the world. But, if there are no other agents near the photon, then there is no way to pass along third-person information about the photon's path. This means there will be no clear idea of which slit the photon goes through.

As a result, the LoP Interpretation says that the photon does not pass through both slits as a wave. It passes only through one slit, but there is not enough third-person information to tell us which slit. Thus, the interference pattern has nothing to do with the photon changing from wave-like to particle-like behavior. There is simply no way to know the path that the photon takes.

Recent experiments validate this interpretation. Two recent experiments have shown that photons do appear to go through only one of the slits, not both. We simply cannot determine which path without making a measurement (reported in Francis, 2012, and Francis, 2011).

This lack of information about which path is taken affects the photon because it does not know its exact place in the world for that moment in time. It is as if the influence of the field of space is suspended and the photon is free to choose whichever path it likes. Thus, only second-person relationships determine what happens. This is why the two possible paths exist as superpositions and both possibilities influence the outcome. (More on this in section 4.9). But, as soon as other agents, such as particles, other photons, or cosmic rays pass through the equipment, a sense of the photon's path emerges. And as it does, the photon's choices decrease, because the field of space now gives the photon a clearer picture of the path it is taking. This is why the interference pattern fades.

This describes how the process of decoherence works, according to the LoP Interpretation. This does not yet solve the measurement problem, however. For that we need one more postulate.

4.9 Postulate 9: First-Person Perceptions Cause the Wave Collapse

We now get to the heart of the measurement problem in QM: Why are there always specific outcomes whenever we make a measurement and how are those outcomes determined?

This is a thorny problem for quantum theory because it cannot be explained by the gradual linear changes of quantum states that follow the Schrödinger wave equation. It is as if the wave function is bypassed or turned off for a moment, but only for the moment when the wave collapses.

> The measurement problem…is one of the most famous and stubborn in quantum mechanics. Often it is characterized as "the collapse of the wave function," indicating that when a measurement is performed, the result will be one of the eigenvalues of the measured observable. But this description fails to convey the depth of the difficulty. That the wave function (quantum state) collapses when a measurement is performed is indeed surprising, but it is not obviously inconsistent. The real crux of the measurement problem is not simply that collapse occurs, but rather how it occurs.
>
> It can be shown (without undue difficulty) that collapse cannot occur due to "regular" time evolution by the Schrödinger equation…. That is, we must suspend the Schrödinger equation during a measurement, so as to effect the collapse. But must not a measurement simply be a particular kind of physical interaction – different in details, but not in kind, from non-measurement interactions? What, then, can justify "turning off" the Schrödinger equation only during a measurement? As John Bell asked, "are we not obliged to admit that more or less 'measurement-like' processes are going on more or less all the time more or less everywhere? Is there ever then a moment when there is no [collapsing] and the Schrödinger equation applies?" This, more so than collapse per se, lies at the heart of the measurement problem. (Bowman, 2008, pp. 30-31)

We now have the tools to answer these questions. I already provided a story about how this looks from the level of human consciousness. This offers a degree of clarity that gives us added insight into what is happening from an insider's perspective. Here is what I wrote in section 3.3.4:

> The most notable feature of the middle level is defined by **first-person perception**. This is what enables quantum states and unconscious processes to cross over into actualized events and conscious access, making them visible to third-person analysis. This is the source of all tangible activity. Internal agency originates at this level, allowing quanta and living organisms to act as individuals and exchange energy.

The last sentence is the most important when applying this principle to the level of quanta. We indeed see "internal agency" displaying itself when events are actualized. For example, this is when we see a photon clearly hit one spot on a screen. All events that involve energy transactions also display this property of individual quanta because the energy must be carried in packets. The reason for this, according to LoP theory, is that internal agency requires first-person choices. In other words, we must place our attention on one possibility (out of many) and choose it, before it can happen. Everything leading up to that moment is the evolution of the possibilities that influence us. These possibilities happen purely at the quantum level – meaning at the level of personal relationships between sentient agents. When a choice, which is an act of perception, leads to an empirically detectable action, we see a wave collapse.

We now need to explain how this works at the quantum level based on the postulated principles of perception above. Fortunately, we have just learned a valuable new insight: It takes energy to go against the norm of third-person fields. Let's look at this in more detail.

Second-person relationships evolve in a linear way, the same way that quantum states evolve, as described by quantum formalism. The reason for this is that one-on-one relationships evolve in response to the sentient agents involved, because the perceptions of their relationship with each other continue to change. We naturally feel a loss of self when we are with our closest friends and become wrapped up in the relationship experience. This is why we see no sign of internal agency with quantum states and why they seem wave-like when they are not being measured or analyzed.

Third-person relationships, on the other hand, evolve through the decoherence process, producing the public field of space, and other fields as well, such as particle fields and the electromagnetic (EM) field. As the number of sentient agents in those fields grow, the fields grow stronger in the pressure they apply to follow the norm. Fields, by their nature, according to the LoP Interpretation, always push for stasis. The pressure is felt unconsciously and appears more as something in the background, not the foreground. This is why we see no signs of individuality in fields themselves, except when field particles interact as sentient agents.

While the evolution of quantum states (wave-functions) and the evolution of fields are both well defined by quantum formalism, the conflict between them is not. However, the fact that there is a conflict between them becomes immediately clear with the LoP Interpretation. This conflict can be illustrated informally (and surprisingly) by Shakespeare's story of Romeo and Juliet (adapted from Marman, 2016, pp. 225-226):

> Romeo grows up in one family, Juliet in another. Each family has its own perceptual field formed by generations of ancestors. The two families have been at war, hating and despising each other. Romeo and Juliet fall in love, against the laws that govern their

> family behavior, and against everything they have been taught since they were children. They are suddenly thrust into an impossible conflict.
>
> The power of tradition seems absolute, like a law of nature that must be obeyed. However, third-person fields cannot compete with love. The bond between Romeo and Juliet goes deeper. They love each other. So, they stop obeying the teachings of their ancestors. The laws of their families can no longer control them because they feel a strong desire to make different choices.
>
> Suddenly, they find themselves in a situation with dangerous possibilities. These are superpositions. The outcome could take many different paths. Meanwhile, each family tries to force obedience to their laws. Their traditions must be followed. Romeo and Juliet break with tradition because they refuse to be parted, resulting in their deaths. The play ends with both families realizing the wrong that has been done. Their fields are forever changed by a boy and girl who fell in love.
>
> Shakespeare was right: Second-person bonds are more powerful than third-person fields. Personal relationships are stronger than outer laws. And he was right that the two can be at odds. Our private lives are often in conflict with the public and political world we live in. And the lesson here is that our public world should recognize that, whether it likes it or not, it must adapt to the choices of people.
>
> Fields define how particles should act, but third-person social norms cannot control what happens when people fall in love. Personal experiences affect them deeply. They find themselves involved in the back-and-forth dance of entanglement. They share a mutual relationship that is stronger than any field.

Second-person relationships have a significantly stronger influence over quanta than the norm of third-person fields. However, it takes effort – real energy – to go against a third-person field. Or, to put this another way, sentient agents can break with the norm and choose to form a new reality in the world – a new reality that is not dictated by external forces. However, they can only accomplish this through a concerted effort.

This is why a wave collapse requires energy to be exchanged, because the whole third-person field must be altered. And, just as we see in the story of Romeo and Juliet above, both agents in a second-person relationship must decide jointly to make this happen together. Since decisions are always first-person actions, this means that both agents must choose to act in concert. Their joint action changes the public world. This is how ripples in fields are created, as the fields are forced to adjust to the new reality.

The Schrödinger equation “turns off” because there are no longer any embryonic perceptions and half-formed feelings about the many personal relationship possibilities between the two sentient agents. Both agents have recognized and selected one of the possibilities together. In order to break with tradition, those perceptions must trigger an action strong enough to alter the external field. Only acts made jointly this way can create an event in the world. Such an act resets the wave function because the world changes in an irreversible way. The old possibilities no longer exist because the situation has changed. This also changes their second-person relationship irreversibly. As a result, a new story now begins to evolve based on new possibilities.

4.9.1 A Formal Model for Wave Collapse

This describes why and how the wave function collapses. But this is only an explanation suitable for the human level. We need to formalize this process in a way that applies to quanta. Fortunately, all the hard work has already been done. This was the surprising discovery I made, in 2015, when I ran across Ruth Kastner's formal interpretation of QM (Kastner, 2013), called the Relativistic Transactional Interpretation (RTI). Her approach is an off-shoot of the Transactional Interpretation of QM (TI) developed in the 1980s by John Cramer (1986).

Cramer was inspired by "Wheeler-Feynman absorber theory," developed by Richard Feynman and his thesis advisor John Archibald Wheeler, which offers an alternate model for EM energy. As explained by Kastner (2013), Feynman and Wheeler showed that the radiation of light can be viewed as waves sent out from emitters that move forward in time and waves sent out from absorbers that move backwards in time. When the two waves match and align exactly, the combination creates a transfer of energy from emitter to absorber. This process is called a "handshake." A handshake is the "coupling" of the two waves that create a transfer of energy (pp. 44-45).

Cramer realized that if this is a valid representation of how energy is transferred, then quantum formalism should include both the forward moving and backwards moving waves. To use only the wave that moves forward in time, which is the traditional method, is to only include the story of emission. This does not describe the process of absorption. It tells only half the story.

This idea that a wave function travels backwards in time is hard for many scientists to swallow, which is why the TI interpretation has not been widely accepted. However, Kastner solves this problem by saying that these waves do not exist in space-time. Only the transactions of energy take place in space-time. In other words, quantum wave functions (the possibilities) exist outside of the space-time dimensions.

Kastner shows that the "offer waves" that come from potential emitters, and "confirmation waves" that come from potential absorbers, are quantum wave functions. In other words, these exchanges represent a quantum relationship, and these are quantum states that do not exist in space-time.

> Offer and confirmation waves are physically real, but sub-empirical, possibilities. [Offer waves and confirmation waves] are interpreted ontologically in [RTI] as *physically real possibilities*. In this context, "real" means physically efficacious but not necessarily *actualized*…. [T]hink of [these waves as] the submerged portion of [an] iceberg…. [F]rom the vantage point of the deck of a ship (representing the empirical realm), we cannot see the submerged portion, but it certainly supports the visible portion and therefore cannot be dismissed as "abstract" or "unreal." In Bohr's words, these entities "transcend the spacetime construct"; however, rather than dismiss them as Bohr did, I allow that they are physically real, even if sub-empirical.
>
> [Offer waves and confirmation waves] are necessary but not sufficient conditions for an actualized event. The remaining necessary condition for an actualized event is that one particular transaction be actualized. (Kastner, 2013, p. 68)

I was stunned to see how perfectly this aligns with the LoP Interpretation. Kastner says that she does not claim to know the material nature of these quantum *possibilities* (p. 67). However, the postulates above tell us that these are relationship possibilities between sentient agents. They do not exist in space-time because they cannot be seen by outsiders. They exist only between agents.

The "coupling" of offer waves and confirmation waves also fits perfectly with the inner dynamics of relationships between sentient agents. Even the idea that wave functions pass back and forth between quanta fits with the postulates listed above. Only when they align with and complement each other can these *possibilities* be reinforced, and only when they are reinforced can the relationship evolve.

However, all possibilities do not create actualized transactions of energy. In fact, real transactions of energy are rare, and there is no way that outsiders can predict which relationship is going to produce an actualized event. Only a small percent of these quantum possibilities are actualized. Kastner (2013) points out that the coupling factor between individual photons and electrons, where an electron absorbs a photon, is about 1/137. The same coupling factor exists for an electron to emit a photon. Therefore, the probability that an actualized transaction will occur between two electrons is $(1/137)^2$, which is about 0.005% (pp. 65-66).

This example graphically illustrates why it is the square of the quantum possibility that gives us the probability of actualization – because the offer wave probability must be multiplied by the confirmation wave probability and both waves must be identical for them to couple. This is the exact condition required by the postulates of perception described above. Possibilities in a relationship must be agreed on exactly before they can act in concert.

Traditional interpretations of QM cannot explain why squares of probabilities are needed. It was determined empirically by Max Born and is now accepted as a postulate of quantum formalism. This is one of the significant advantages of the TI interpretation: It shows why "Born's Rule" exists. (For a detailed explanation see Kastner, 2013, pp. 53-55).

> [I]n most prevailing interpretations, the Born Rule is either simply assumed as part of the mathematical machinery…or it is given a pragmatic, 'for all practical purposes' account, which in my view, fails to do justice as the crucial link between theory and concrete experience. The Born Rule constitutes a deep mystery for all prevailing interpretations…other than TI. (Kastner, 2013, p. 35)

We can now add the LoP Interpretation to the list of interpretations that agree with this explanation.

The coupling between photons and electrons shows us something else as well. When second-person relationships form, according to LoP, attraction or repulsion develop, the same as we see in relationships between living creatures (Kastner, 2015, pp. 86-87).

Physicists model two electrons repelling each other as a virtual photon passing between them. However, as explained above, only 0.005% of the time will two electrons actually be physically repulsed away from each other. In those rare cases, the photon that passes between the electrons is said to be a "real" photon, because it carries real energy in space-time. The other 0.995% of the time, a static force of repulsion exists, but no actualized transfer of energy takes place. In those cases, the photon is said to be a "virtual" photon because it never exists in space-time.

In other words, static forces arise from relationship exchanges that exist only in the quantum world. Forces that accelerate objects are different: they exist in space-time. Static forces are different from actualized forces, but there is a clear relationship between them: Before energy can flow, there must be a buildup of static force. This is when virtual photons can pass between potential emitters and absorbers. Therefore, it all begins with attraction and repulsion.

When static charges grow strong enough, the story changes. Electrical sparks fly through the air or beams of light are created. Transactional events can only happen when emitters build up more potential energy than absorbers. This means that the relationship is no longer equal. That is why energy flows from the emitter to the absorber. This is what is needed to create an event that changes the EM field and the field of space. (More on this below).

What makes radiant energy different from static forces? Kastner (2015) offers a clear interpretation. She says that the mystery comes down to a simple fact: There is a threshold that a virtual photon must cross before it can move from being a mere possibility to a real photon.

> This number, 1/137, is a very well-known number in physics. It is called the "fine structure constant." The fine structure constant is important because it characterizes the strength of the electromagnetic interaction between charged particles… [I]n this book, the fine structure constant gains an interesting new physical meaning: it expresses the likelihood that a photon will advance from being merely "virtual" to being…actualized. (p. 101)

Feynman (1985) defines the fine structure constant in a similar way: "the [probability] amplitude for a real electron to emit or absorb a real photon" (p. 129).

This graphically illustrates the existence of an energy threshold needed to change the third-person EM field. This validates the LoP theory that energy is needed to go against a field. A quantum of momentum is also needed to change the field of space. However, LoP theory takes this further, because it predicts that the amount of energy needed to change a field will grow as more sentient agents join a field. In other words, the fine structure constant can change. This prediction comes from the fact that, as the number of charged particles in the EM field grows, so will its resistance against change. This idea of thresholds plays an important role with all of the four forces of physics, according to the LoP Interpretation (Marman, 2016, pp. 446-450).

Kastner (2013) says that the key advantage of the Transactional Interpretation over all other "collapse" type interpretations is that the meaning of "measurement" is clearly defined in physical terms, without having to appeal to the consciousness of an observer of the measurement. Once again, the LoP Interpretation is in agreement.

> How is this achieved? Very simply, by taking into account that *absorption is a real physical process*. This is certainly the case in relativistic quantum field theories: one cannot arrive at a correct empirical prediction without taking absorption into account. Indeed, absorption (i.e., annihilation) is a key element of the definition of the field operators used in any calculation of probabilities of empirical events. Such calculations routinely involve taking expectation values in which quanta are created and quanta are destroyed. If such calculations refer to anything physical (the basic realist assumption),

> both processes are physical processes. However, for the past century or so, interpretations of non-relativistic quantum theory have completely disregarded the absorption process, granting physicality only to emission processes … They have thus considered non-relativistic quantum mechanics – which is just a limiting case of quantum theory – only in a particular form (as applying only to emission) and in isolation from its relativistic application; and this, I suggest, is what has prevented the ability of such interpretations to account for measurement in physical terms.
>
> Specifically, a measurement or determinate event (i.e., it does not have to be a formal "measurement" conducted by an observer) occurs whenever annihilation of one or more free quanta occurs. In terms of relativistic quantum theory, absorption corresponds to the action of annihilation operators on free quanta, just as emission corresponds to the action of creation operators. (pp. 55-56)

What Kastner is saying here is that, first, QM needs to include the process of absorption, not just emission, and, second, a relativistic model of quantum theory is needed to fully explain what a wave collapse means. The difference between relativistic models and traditional non-relativistic interpretations is that relativistic models show how forces emerge from quantum interactions and obey Einstein's theory of relativity. Relativistic models describe quanta, such as virtual photons, passing between charged particles. Virtual particles are being created and destroyed all the time, even in the voids of space where no real particles exist. Quantum field theory describes this process in great detail, and it is necessary to include the effects of virtual particles to get accurate results. The process of calculating the impact of virtual particles is called "renormalization."

To put this in simpler terms, physicists already acknowledge that quantum states are being created and annihilated all the time. They are sometimes modeled as virtual particles, but they can also be treated as quantum wave functions that do not exist in space-time. Therefore, a wave collapse is actually and truly an annihilation of a wave function through the process of absorption.

When a photon is emitted from an atom, the photon is literally being created. When it is absorbed, such as when it lights up a point on a screen, the photon literally ends its life. The photon carries with it energy and momentum from an emitter to an absorber. This is an event that takes place in space-time. The photon is, therefore, the space-time manifestation of a quantum relationship.

This physical model is a perfect fit with the postulates of perception listed above. We now have a theory that starts with underlying principles (postulates) and includes a model-based theory as well. Combining these two, the LoP Interpretation can clearly explain the wave collapse process.

While Kastner's interpretation (RTI), offers a working model that has rigorously been shown to be consistent with quantum formalism, it still falls short of providing a full explanation for why and how one of the quantum state possibilities is selected to become an actualized event, although it comes closer than any other interpretation I have seen in describing what is happening. Kastner even comes closer than Cramer's Transactional Interpretation (TI) because she shows that the process begins outside of space-time, in what she calls "pre-spacetime" (PST).

> If we take the domain of transaction formation as PST rather than spacetime, then an account cannot be given in terms of any causal process within spacetime in the usual sense…since the latter are confined to spacetime. Instead we need to turn to a similar situation in physics in which there are apparently many possibilities but only one is realized: "spontaneous symmetry breaking" (SSB). (p. 76)

This makes perfect sense and is in agreement with LoP theory. There can be no causal processes behind the wave collapse. And SSB is a good model to turn to. Kastner then describes a number of examples of SSB, including a study of the pattern created by a drop splashing into a bowl of milk. The pattern of the splash is never exactly symmetrical. When the authors of a study on milk splashing ask why it is not symmetrical, they answer that it is because of imperfections. Nature is never perfectly symmetric. Kastner (2013) comments:

> Thus, the apparent answer of the authors to the question of what causes the system to end up in a particular state is: quantum fluctuations… It appears that, strictly speaking, when considering symmetry breaking in the classical domain, one could always point to some external cause of this type, even if only a random quantum fluctuation. So when the authors say that "the actual breaks the symmetry of the potential," they are not yet describing the quantum domain which [RTI] seeks to describe. (p. 81)

Kastner rightly points out that quantum fluctuations could indeed offer a valid explanation for why the symmetry is disturbed in the domain of classical physics. And she is right that this explanation does not work for the quantum domain where one quantum state is chosen over others. She then refers to a famous purely quantum case of symmetry breaking: the Higgs field. And here we can see that a full explanation falls short:

> If we want to try to follow the same procedure and to seek a specific cause…for the choice of one of the infinite set of possible vacuum states, we either have to suppose that it also stems from fundamentally indeterministic quantum fluctuations of the vacuum, or postulate fluctuations in some deeper realm that lies outside any current theory…. The only alternative is to postulate that SSB in the Standard Model requires a "many worlds" interpretation, in which SSB gives rise to many possible worlds.... But this is certainly not the usual approach. (p. 82)

To summarize, Kastner is saying that when there is a wave collapse, one way of explaining how one of the possibilities is selected could be the influence of quantum fluctuations. If this is not the cause, then it could come from "fluctuations in some deeper realm that lies outside of any current theory," or we need to invoke the Many Worlds Interpretation, which says that each of the possibilities is selected in a different parallel universe.

Unfortunately, quantum fluctuations cannot be the cause. It is fine to use this as an external force when dealing with classical events such as splashes of milk. Or you could use this to explain why a knife perfectly balanced on its point, in a complete vacuum, will always fall eventually. But this does not work as an explanation for a wave collapse because quantum fluctuations are nothing more than the fluctuations created by virtual particles being created and destroyed. These are the same quantum states that occasionally cross over to become actualized as real particles.

The question we are trying to answer is why one, out of the many possible quantum states, crosses over to become real. We cannot use other quantum states as a causal explanation because they are just more quantum possibilities. They will simply shift the weight of the possibilities and change the odds for which state is selected. They will not trigger an end to all other quantum possibilities when only one becomes actualized.

It is also worth adding that the whole reason the Many Worlds Interpretation is proposed is because there has been no explanation in quantum theory for why many quantum states would suddenly collapse down to one actuality. Or to put this another way, there has been no explanation for why quantum possibilities should ever end. However, as Kastner explained above, as soon as we move to a fully relativistic model of quantum interactions we see that quantum possibilities are created and annihilated. They spring up and disappear because they are relationship possibilities, and some of those possibilities will indeed disappear when the wave function collapses.

The LoP Interpretation offers a full explanation for why and how the collapse process works at the human level. We see it happening every day in human society. For example, out of the countless cases of flirtation that take place in a university or a company, only some will turn into real friendships or affairs. The flirtations can be considered "offer waves." Obviously, most offers are not accepted, but the ones that generate a complementary response can grow into relationships.

However, friendships and even affairs are private exchanges. Only one out of hundreds will cross over to marriage. Marriage is different because it requires a public change of state. It is recorded in a court of law and legally changes the responsibilities of the couple when it comes to ownership and taxes, etc. Marriage also changes the relationships between families of both spouses. These are public changes, as Romeo and Juliet discovered. And all the other possibilities (flirtations) of marrying other people end abruptly in that moment when they make their wedding vows.

When looking at the shift from private relationships to public marriage, it is easy to see what is needed to make the change: Two people need to jointly make a decision together. Outside forces cannot make it happen. There are many outside influences, but the act must be made by the couple.

If these relationships at the human level are quantum states, and marriage represents a change of state in human society, then, according to the LoP Interpretation, relationships between quanta must follow the same pattern. Therefore, postulate 9 states that **a wave collapse is the shift in a second-person relationship from a private, personal possibility, to a third-person public actuality – from a quantum state to a space-time event. It requires two sentient agents jointly making first-person choices to change the state. This requires real energy and a change in momentum. And when it occurs, it brings an end to other possibilities.**

4.9.2 Problems Solved Using the Transactional Model

This model gives us added insights into a number of problems. Let's take a look.

4.9.2.1 Changes in Quantum States of Measuring Equipment

Quantum formalism says that, when a measurement takes place, the quantum state of the system being tested suddenly changes. The system being tested then evolves from that state until it is changed by another measurement. We can now see that this change is governed by the relationship between the system and the equipment because the equipment is designed to measure a specific state. This compels the system being tested to exactly match the state of the equipment, to make a "handshake." This gives us a valuable insight into understanding quantum formalism, as we will soon see.

4.9.2.2 The Mind-Body Problem

When psychologists observe the neurological process of "conscious access" (see section 2.2), they recognize the importance of attention. The human being must move their attention to a possible event before it can become conscious. However, from the above discussion we can now see that this is not the complete story. To create a physical action, a human being must jointly act in concert with the cells of their body. Both must agree to act jointly in order to exchange real energy. We cannot make our muscles move by ourselves.

This solves **the mind-body problem** that has troubled philosophers for centuries. It shows how a sentient agent works in concert with the cells of their body, when they jointly make possibilities become actualized events. Biologists can see the energy exchanged when muscles move. However, they have no good explanation for how that energy is triggered when a person decides to move.

Our new model shows that human beings cannot make this happen by themselves. A relationship between a human being and the cells of their body is needed. They must jointly agree before real energy can be exchanged. This is why neuroscientists see the brain getting ready before an action (Marman, 2016, pp. 299-307). Alignment between mind and body happens unconsciously, exactly as LoP theory suggests, because these are second-person quantum exchanges before the actualized exchange of energy. Thus, second-person relationships are dynamic, and they have a real impact, but they are intangible to outsiders. (More on this in section 6.2).

4.9.2.3 Schrödinger's Cat Paradox

Another problem solved by Kastner's model, and the Transactional Interpretation, is the famous **Schrödinger's Cat paradox**. Since it is so well known, I will only explain it briefly. The problem starts with a radioactive atom that is in a superposition state of being "decayed" and "not-decayed" at the same time. If this atom, when it decays, emits a radioactive particle, and this particle triggers a detector that releases a hammer that swings and breaks a vial of poison, killing a cat, then according to traditional interpretations of QM, the detector should also be in a superposition state, along with the hammer, the vial of poison and the cat. Does this mean the cat is both alive and dead at the same time? That seems ridiculous, and this is exactly the point Schrödinger was trying to make when he proposed this thought experiment.

The Transactional Interpretation settles this matter easily. The problem disappears as soon as you include the absorber's role. The absorber's side of the story changes everything. The superposition state of the atom collapses as soon as the radioactive particle is absorbed by the detector. Thus, the cat is not in a superposition state. Only the atom, which is the emitter, and the absorber in the detector are in superposition states, until the radioactive particle is emitted and absorbed (from Marman, 2016, p. 233).

The nine postulates, above, add even more clarity to this puzzle. The radioactive atom and the atoms in the detector are sentient agents that form relationship possibilities with each other. This is why they share the superposition states of "decayed" and "not-decayed" as possibilities. However, the hammer that breaks the vial of poison, and the vial, are both classical objects. In other words, they are conglomerates – not sentient agents, so they cannot form quantum relationships. Yes, each of the individual atoms in the hammer and vial can form quantum states with possibilities, but this in no way alters the behavior of the hammer, the vial, or the poison.

We also know that as long as the cat is alive, it is a sentient agent. But cats do not form personal second-person relationships with atoms, so it never shares the superposition states of "decayed" and "not-decayed." As I said before, we should not confuse a wave collapse at the level of quanta with a wave collapse at the level of living organisms. For the same reason, we should not confuse quantum relationships between living organisms and quantum relationships between atoms. The classical world emerges from conglomerates because they are far removed from the personal relationships of individual sentient agents. That is when third-person reactions become dominant.

4.9.2.4 Delayed Quantum Eraser Experiments

Kastner's model also solves one of the most confounding experiments in quantum physics: **the delayed quantum-eraser experiment**. In this experiment, it appears as if a measurement of a photon made later alters the state of a second photon measured earlier. In other words, it appears to act backwards in time. The key to understanding what is happening is that the photon detected later and the photon detected earlier must be entangled. If this is true, then the solution is simple. Yes, it seems as if information flows backwards in time, from the absorption of the first photon detected later, because a confirmation wave does appear to flow backwards in time. But, in fact, the quantum state that they share does not exist in space-time. Thus, the time paradox is resolved. (For a detailed, formal discussion, see Fearn, H., 2015).

4.9.2.5 Another Look at the Two-Slit Experiment

With this new insight, we can also give a more complete description of the two-slit experiment than what I gave in section 4.8.4: An emitter forms a second-person relationship with all potential absorbers on a screen. TI says that these offer waves look for matching confirmation waves. LoP theory says that these are vague perceptions and half-formed feelings that only form relationships when they align. These are second-person relationships, which are quantum states, that create static forces of attraction or repulsion. This is what happens when potential energy grows in the emitter.

A photon is not emitted until a perfect match is found with an absorber, and both the absorber and emitter form a "handshake" that couples their first-person choices together into one joint action. The virtual photon passing between them then crosses over to become a real photon that carries real energy and lights up the spot of absorption on the screen.

However, while both the location of the emitter and absorber become clearly defined by this action, the path that the photon takes is unknown, as I explained in section 4.8.5. As a result, the relationships between the emitter and all of the possible absorbers exist at the same time and influence the outcome. These are virtual photons that pass through all possible paths to all possible absorbers. And they act as superpositions that interfere with each other, creating the interference pattern.

This is why Feynman was right to say that we can calculate the probabilities by adding together all of the possible paths. This does not mean that a real photon actually takes all possible paths. The quantum states are only weighing all of the possibilities before one is selected and actualized.

This is consistent with what the “Taking Heisenberg’s Potentia Seriously” paper says:

> Feynman famously re-derived the quantum laws in his ‘sum over paths’ approach by taking a quantum system as taking ‘all possible paths’ from an initial prepared position to a final detected position.... Clearly, such a system does not *actually* take distinct and mutually exclusive paths; its ‘taking of all possible paths’ is properly regarded as a set of possibilities, not actualities… We suggest that the efficacy of his possibilist approach in yielding a formalism that was initially arrived at by heuristic mathematical data-fitting is evidence that it captures some ontological feature(s) of reality.
>
> Thus, we propose that quantum mechanics evinces a reality that entails both actualities (*res extensa*) and potentia (*res potentia*), wherein the latter are as ontologically significant as the former, and not merely an epistemic abstraction as in classical mechanics. (pp. 7-8)

Kastner (2013) noted this same confirmation of Feynman’s calculation of all possible paths (Kastner, pp. 84-87). And I (2016) also arrived at the same conclusion before reading Kastner’s book (Marman, 2016, pp. 222-224). So, you can see why Kastner’s solution was such a surprising discovery for me, because it offers a model that matches the postulates of perception that I had uncovered.

Kastner started from a completely different origin: John Cramer’s Transactional Interpretation and quantum formalism. She converted TI into a fully relativistic model. On the other hand, I started with similarities between the behavior of quanta and the behavior of living organisms, leading to principles of perception that underlie both of them.

Naturally, this complementary match between the LoP postulates of perception and RTI’s formal model struck me as powerful validation. (In other words, these two possibilities match so well that it increases the reality of both of them, the same way a quantum handshake crosses over to become an actuality). This sense of validation grew even stronger when I ran across this footnote in one of Kastner’s books: “One might wonder whether quantum entities are endowed with some rudimentary form of consciousness. Such considerations are interesting and important, but beyond the scope of this book” (Kastner, 2015, p. 127).

4.9.2.6 Space and Time Revisited

With this combination of underlying principles and a functional model, we can offer even more insight into what happens during a wave collapse. For example, when looking at this in terms of Einstein’s theory of relativity, we can see that no time passes for the photon, from the moment of emission to the moment of absorption, because it is traveling at the speed of light. The only thing that makes a photon real is that it carries real energy and changes the EM field (by creating a ripple), and it applies a quantum of real momentum that alters the field of space.

A transactional event is a unit of action. Bohr called it a quantum of action. What makes this even more interesting is that, even though the actual positions of the emitter and absorber are all relative, depending on the reference frame of outside observers, and the time of the event is also relative to outside observers, the space-time interval is the same for all outside observers. As Kastner (2015) explains below, this means that a space-time event is something that all observers can agree on. This makes sense, in LoP theory, because such an event changes the whole third-person field of space:

> If a well-defined time interval were applied to an object with well-defined energy, this would contradict the [Heisenberg uncertainty principle]. (p. 165)
>
> Thus, the most accurate way to understand the time-energy version of the [Heisenberg uncertainty principle] is not really in terms of time intervals, but rather in terms of change: if an entity has a completely precise energy value, there is no observable change in the entity characterized by that energy. However, there are changes in the emitter that emitted it and in the absorber that absorbed it: one lost energy, and the other gained it… This, in turn, allows us to define a time interval corresponding to the two events. This leads to the crucial point that a time interval is created by the transfer of some exact amount of energy from one entity to another in an actualized transaction. (pp. 165-166)
>
> We've noted above that, in the transactional picture, a time interval is created by the delivery of a quantum of energy from an emitter to an absorber. Interestingly, this corresponds to a more esoteric but standard physical account of the relationship between energy and time: Energy is the creator of time intervals. (p. 167)
>
> At this point, you may have guessed that a similar relationship holds for position and momentum. Indeed, it's also true that momentum is the creator of spatial intervals. As with energy and time, a transferred quantity of momentum (basically motion) corresponds to an interval of space; and without that momentum, there is no spatial interval. (p. 168)
>
> [R]elativity tells us that neither spatial nor temporal intervals, individually, are absolute quantities. They are defined only relative to the states of motion of observers who can see the emission and absorption events marking those intervals. And the quantum's amount of motion itself is not absolute; that is, whether or not a quantum has momentum depends on the frame in which it is described. (p. 169)
>
> Nevertheless, there *is* an absolute quantity, one which is the same for all observers regardless of their relative motions. It is the spacetime interval… The spacetime interval is basically the difference of the (squares) of the temporal and spatial intervals as measured in any particular frame. (You take the time interval between [emission and absorption], multiply that by the speed of light, square it, and then subtract from the square of the distance between [emitter and absorber]). It turns out that despite the differing perspectives of observers in different states of motion, the spacetime interval is the same in all of them. It is the one measurable spacetime quantity that they can all agree on… And the spacetime interval is what is created in an actualized transaction. (pp. 169-170)

According to Kastner, space-time is a tapestry woven from space-time events created by changes in momentum and exchanges of energy. As we can see, these events are quantized.

They are made from discrete transfers of energy and momentum. This means that space-time itself is quantized.

However, according to LoP theory, the field of space is not quantized because it is made from grey comparisons of outsider perceptions from third-person relationships. Yes, every field is made from a finite number of these relationships, but the experience of space and its effect on sentient agents is continuous. As you zoom down to smaller and smaller regions, the field of space does not become more discrete and quantized, it simply becomes weaker and weaker.

In fact, we already have a good example for how the field of space looks when it is weak because this is exactly what happens in two-slit experiments. The interference pattern gradually fades away as more particles enter the area of the experiment because the influence of the field of space increases gradually. This is how decoherence works. This shows that only space-time is granular, not space itself. Space-time is like a glove that fits over the hand of the field of space.

This resolves another obstacle that has been standing in the way of solving the mystery of quantum gravity (how to merge Einstein’s theory of gravity with quantum theory). Smolin (2017) explains:

> These obstacles mainly had to do with showing that on scales much larger than the Planck length, a smooth classical spacetime emerges, which is described by Einstein's theory of general relativity. (p. 228)

A smooth classical space-time is evident at large scales because the field of space guides the positions and momentum of particles, just as the EM field guides electrically charged particles. This is also why water flows smoothly, even though the movement of water is made up of countless discrete actions. For the same reason we can run smoothly, without jerky movements because we are not stopping to think about each movement, but only about the relationship with our body that does the work. Relationships are the influences behind everything in life and nature that flow smoothly. How do we model this? We can build on Kastner’s model.

The influence that fields have on particles is not through offer waves, because offer waves describe only what is happening in second-person relationships. There is no reaching out of hands like we see in personal relationships. The confirmation waves in third-person relationships come from every agent in the field. These are confirmations of other outsider perceptions. This is how a norm is created. No offer waves, only confirmations. The waves do not need to align exactly for them to converge because they are outsider perceptions, none are private, so they naturally converge. However, agents must be entangled through third-person relationships before a field affects them.

Putting this another way, the interactions between a field and the particles that live in that field only exist in the quantum realm, not in space-time. There are no potential emitters and absorbers, there is only third-person entanglement between all of the members of a field. This is what creates the field. Real energy is never exchanged. The inertia that a real particle experiences when it is coupled to the field of space is a “static” force, like attraction and repulsion between charged particles. However, the difference between inertia and static EM forces is that EM attraction and repulsion, when it grows strong enough, can cross over to become space-time events, but the static force of inertia only resists actions, so it can never cross over into space-time. This is how quantum fields work, according to LoP theory, using Kastner's model.

Most physicists say that we can look at fields as if they create quanta, or we can look at quanta as if they create ripples in a field. Both are mathematically equivalent. And the interactions between charged particles and the EM field can be modeled as a field effect, or as if the wave function of the particles interact with themselves (through offer and confirmation waves).

This is where the added constraints of the LoP Interpretation become clear: Only one of these two explanations is acceptable. According to LoP principles, only sentient agents can create ripples in fields through second-person relationships. Fields do not create quanta. And sentient agents do not have wave functions of themselves, so they cannot form relationships with themselves. The quantum state of a sentient agent, by itself, is its first-person perception, which is not visible to anyone else. Quantum wave functions only form between sentient agents because they are different from each other. Therefore, the EM field does have an influence on charged particles, but a charged particle has no way of sending an offer or confirmation wave to itself, because it cannot form a relationship with itself.

4.9.2.7 The Damping Effect in the Field of Space

This issue goes to the heart of the main conundrum of QM: Why is all of matter and energy quantized? Why is matter made up of individual particles? And why is energy always carried in packets? The problem here is not to explain bodies, it is about explaining the internal agency that we see in particles, the same as the internal agency that we see in living creatures. How can a field or a society create human beings or give even the simplest organisms their internal agency?

This is exactly the problem with the current theory of decoherence: It cannot explain how distinct forms emerge from the wave function. Nothing in the wave function can explain where distinctions come from. Yet those distinctions are necessary for entanglement – and, therefore, decoherence – to work. Therefore, fields are outcomes, according to LoP theory, they do not create particles.

This is interesting because it was Feynman who first discovered that the field effect could not be eliminated by absorber theory. Fields exist as something separate from emitter-absorber events.

> Feynman's motivation for his direct action approach (Wheeler–Feynman absorber theory) had been to eliminate the electromagnetic field as an independent entity, and he later decided that this could not be done because of the need for self-energy. (Kastner, 2013, p. 51)
>
> [T]he Wheeler–Feynman approach to dealing with classical radiation theory fell out of favor because it assumed that a radiation source could not interact with its own field; but this "self-interaction" or "self-energy" was found to be necessary, at least at the quantum level, for certain known empirical effects such as the Lamb shift. (Kastner, 2013, p. 50)

In other words, Feynman was hoping that the direct exchange between emitters and absorbers could account for all of the known aspects of EM radiation. However, he eventually came to realize that there was always a small residual field effect that created "radiative damping" that could not be eliminated.

> Dirac (1938) had proposed that damping can be explained by a free field (that is, a field not attributed to any source) in addition to the assumed…propagation due to the charge. While this seemed to account for the observed energy loss, [Wheeler and Feynman] were dissatisfied with its ad hoc character. (Kastner, 2013, p. 199)

Feynman's original assumption that a radiation source could not interact with its own field (with its own wave function) was right, according to the LoP Interpretation. However, the field that Dirac proposed, which creates a damping effect, no longer needs to be seen as ad hoc because we found its origin: It is created by third-person relationships. In fact, these relationships create exactly the damping effect that Dirac described because they resist forces of change.

4.9.2.8 The Uncertainty Principle Resolved

This new insight into how the field of space is altered by actualized exchanges of energy and momentum gives us an added explanation for Heisenberg's uncertainty principle, because it shows us that first-person choices and actions made in concert are stronger than any field.

It is impossible to nail down both the position and momentum of a particle for two reasons: First, because every measurement and wave-function collapse alters the field of space. Since actualized events are happening virtually all the time, the field of space is continually changing.

Notice that this is not about measurements altering the system being tested, which was the point that Heisenberg first proposed. Heisenberg's original view is not how physicists see it today:

> The modern version of the uncertainty principle proved in our textbooks today, however, deals not with the precision of a measurement and the disturbance it introduces, but with the intrinsic uncertainty any quantum state must possess, regardless of what measurement (if any) is performed. (Rozema, *et al.*, 2012. p. 1)

What I am describing is how the field of space itself is altered by measurements. And, as postulate 9 shows us, there is a minimum threshold to this alteration of space that is needed to create an actualized event. This minimum threshold is directly related to Planck's constant, which represents the quantum of action. This agrees with the fact that uncertainty and Planck's constant are related.

The second reason for uncertainty is that measuring position and momentum require two different relationships. This means two different designs of equipment. Each type of equipment gains its information by absorbing at least one particle. Therefore, as soon as one measurement is taken, the field of space is changed by at least one quantum of action, before the next measurement can be made. In other words, as the ancient saying goes, you can never step in the same river twice.

On top of this explanation, we must add what I showed in section 4.8.3, that there are no perfectly well-defined values for the position and momentum of particles before they are measured. As far as I know, this solution to the uncertainty principle, along with the above explanation of the wave collapse process, offers solutions that appear to make the theory of quantum mechanics complete.

And from what I can see, everything I have explained above validates Heisenberg's insight about potentia "standing in the middle between the idea of an event and the actual event, a strange kind of physical reality just in the middle between possibility and reality." This describes the transition from quantum possibilities to actual space-time events quite well. I agree that we should indeed take this idea about potentia seriously, as the paper (by the same name) suggests.

Also, we can better understand the meaning of potentia if we see that they represent the inner dynamics of relationships. Possibilities are the vitalizing source of life in all relationships.

4.9.2.9 Possible Insights for Quantum Gravity

In the 2017 postscript to his book, *Three Roads to Quantum Gravity,* Lee Smolin wrote:

> The fact that we haven't yet solved the problem of quantum gravity, despite much good work by hundreds of very smart and devoted people, is one that deserves some contemplation. Nature is a unity, so surely there is an answer out there. If we haven't found it, perhaps we are doing something wrong…
>
> Here is another way in which I suspect we have been off track. Einstein spoke of two kinds of theories, constitutive theories and principle theories. Constitutive theories posit what the world is made of; they are theories that describe particular phenomena, particular forces or particles. Maxwell's theory of electromagnetism and Dirac's theory of the electron are constitutive theories.
>
> Principle theories set out general principles whose universality requires that every particle and force in nature satisfies them. Special relativity and the laws of thermodynamics are principle theories.
>
> Einstein taught us that we deepen our understanding of nature when we discover new principles. The theories come after the principles.
>
> String theory and loop quantum gravity are both based on hypotheses about what the universe is made of. Thus, these and other of the main approaches to quantum gravity are constitutive theories.
>
> Perhaps we should heed Einstein's advice and look instead to discover new principles. (p. 230)

Postulate 8 is a principle that offers a new explanation for decoherence and how the field of space forms. It suggests that the field of space is a quantum state and it is different from space-time. This offers potential solutions to some of the obstacles in resolving how gravity emerges at the quantum level. Here is another big piece that might help put this puzzle together:

Postulate 9 tells us what happens when there is a wave collapse and there is an exchange of energy. The energy must be strong enough to alter the field of space. This suggests that there might be something else quite remarkable also happening at the same time. Let's look closer.

According to postulate 8, all fields are formed by third-person perceptions converging towards a norm. The influence of each individual outsider perception is weak, but outsider information gains strength when it agrees with other outsider perceptions. Perceptions that do not agree are ignored. They disappear because they do not seem to represent anything real.

One of the key lessons learned by scientists who are looking for a theory of quantum gravity is that gravity appears to be the only force that operates outside of the background of space-time (Smolin, 2007, pp. 80-83). This is one of the biggest reasons why gravity does not play well with quantum theory. Physicists explain it this way: Gravity is background-*independent*, while quantum theory and all the other forces are background-*dependent*.

Einstein proved this quirk of gravity when he showed that it warps space-time. In fact, he said that gravity is no more than a curvature of space-time. This is a valuable clue because LoP theory says that if gravity works this way, something besides third-person relationships must be affecting the shape of the field of space. Postulate 9 tells us that every time there is a wave collapse, the field of space adapts to the change. This is what an exchange of momentum does.

Every time there is an exchange of energy, there is a wave collapse. This means that exchanges of energy could be warping the field of space. This is a promising possibility because Einstein claims that “energy density” is the cause of the gravitational field (Padmanabhan, 2012, p. 8), and countless experiments have validated this.

The new speculative proposal I am offering here is that mass and energy density are followers, not drivers. In other words, mass and energy are gradually pulled in, along with the particles they belong to, by the curvature of space. The true causes of gravity are exchanges of energy. Since exchanges of energy are directly related to energy density in an area, the strength of gravity should be proportional to exchanges of energy as well. Thus, Einstein’s formulas should still hold up.

How does space curve at the quantum level? That is the question that quantum gravity is trying to resolve. A possible answer can be seen if we look at what happens to the field of space when there is a sudden, instantaneous shift. If the locations and movements of sentient agents suddenly shift in a discontinuous way, what happens to outsider perceptions of where those agents are and where they are moving?

If LoP theory is right, the new perceptions will no longer agree with the norm. If this is true, they should be ignored. The field of space only exerts an influence when there is a consensus. This suggests that a small portion of space will stop engaging. It will fall off the map. This might be what happens when an area changes so suddenly that the field of space cannot adapt right away.

Decoherence experiments prove that the field of space adapts at the speed of light. This is how fast location and movement information ripple through the field. However, if there is a sudden shift that is discontinuous, there is no way the field can adapt immediately. This means there is a brief period of time in which that area of space disappears from the field.

What happens to particles that are far away from the disturbance? They will not feel the full brunt of the disruption. In fact, some distance away, particles will see only a gradual sea change, not a discontinuous jolt. So, the rest of the group experiences a contraction in space when a small portion of space disappears, followed by a bulge when it returns. In other words, exchanges of energy act like pebbles dropping through the smooth surface of space, creating ripples.

After I realized the way this seems to work, I was surprised to run across something Smolin (2007) wrote that sounded almost identical:

> [W]hen gravitational waves are very weak, they can be seen as tiny ripples disturbing a fixed geometry. If you drop a stone into a pond on a still morning, it causes tiny ripples that barely disturb the flat surface of the water, so it is easy to think that the ripples move on a fixed background given by that surface. But when water waves are strong and turbulent, as near a beach on a stormy day, it makes no sense to see them as disturbances of something fixed.
>
> General relativity predicts that there are regions of the universe where the geometry of spacetime evolves turbulently, like waves crashing on a beach. (pp. 84-85)

I am suggesting that we need to make one big exception to what Smolin says above: When the change is turbulent, it is lost from the field. Those are the regions of space that vanish. There is no roaring crash of waves, only the sound of silence. Third-person entanglement cannot handle shocks, only gradual changes. Anything too sudden falls off the map of space.

This does not mean that the particles stop existing. No, they clearly still exist. They have not gone anywhere. They simply disappear from the field of space for a while. A few moments later, once the field adapts to the change, a new map is created that reunites the missing agents to the field.

What would be the result of a small area of space suddenly disappearing for a few moments? Is it not the same as space shrinking for an instant? Of course, once the missing agents are restored to the field, space would expand again to make room for them.

However, if there is a continual stream of wave collapses, there will be a continual supply of holes in the field. And we know energy exchanges are happening all the time, because as John Bell asked above (quoted from Bowman, 2008): “are we not obliged to admit that more or less ‘measurement-like’ processes are going on more or less all the time more or less everywhere?” (p. 31). If this is true, it should create a continuing gradient in the field of space.

Can this be the cause of the curvature that quantum gravity is looking for?

If this principle is right, all particles should be affected equally by the movement of the field of space as it continually flows in to fill the holes. The mass of a particle should not matter. Every particle belongs to the field of space, so they should all follow curvatures in space. Even massless photons should be pulled along by the movement of space to fill the holes.

Where would gravity be the strongest, according to this theory? Where more energetic exchanges are present. All particles should be pulled along for the ride. This means that the mass and energy of those particles will be pulled in as well. Large planets and stars will continue to exert a stronger curvature on the field of space compared to the relatively empty space that surrounds them.

Of course, this idea is highly speculative. However, it does offer an intuitive explanation for why inertia and the force of gravity are equivalent, as Einstein proposed. Inertia is the result of particles being weakly tied to the field of space. This is what keeps them moving along. And gravity is what happens when particles are pulled along to follow the field. These are indeed equivalent.

This raises a number of questions. Here is one: If this happens to the field of space, then should we not see the same thing happening to the EM field? The answer is yes. But, the same charged particles that will disappear off the map of the EM field, when they are disturbed by an EM exchange of energy, should also disappear off the map of space as well. Thus, the EM field curvature will exactly match the curvature of space. This shows us why the EM field acts as if it is background-*dependent*.

This leads to a possible insight into what is called the "hierarchy problem," which asks why gravity is so much weaker than all of the other forces, and why gravity acts as if it operates on a lower level of a hierarchy? We now have a possible answer: Gravity is caused by the "peer pressure" of third-person relationships that are weak because they are impersonal. This is the force that nudges all particles to follow the *background* of space. It is a "static" quantum state influence. The EM force, on the other hand, does not even notice changes in the background, because the EM force is all about highly dynamic second-person relationships that must be strong enough to alter the field of space. This means that the EM force is made up of exchanges of energy, while gravity is not.

Here is another question: If gravity works this way with quanta, then should we not see the same gravitational effect at the level of living organisms? The answer is yes. Here is an example: What happens when there is a major disaster, such as a hurricane, earthquake, or terrorist attack? It creates a severe jolt to the fabric of society. This is no surprise. However, the response is always amazing to watch, because the disruption pulls communities together. People quickly move to help each other, to restore and strengthen the bonds that hold them together.

Another example is when there is a death, birth, or marriage, in a family. These are sudden major changes. A death is a discontinuous loss. Birth and marriage are discontinuous gains. And, in all these cases, family members feel the need to regroup, to welcome new members and acknowledge losses. They are pulled together to reinforce and adapt to sudden changes in the family.

This is of course a speculative theory, but it also turns out to be consistent with recent theories that suggest gravity may be an "emergent entropic force" caused by entropy density (Verlinde, 2011, Padmanabhan, 2011, and Padmanabhan, 2012). What I am proposing is consistent with those theories because entropy density is a good description of the degrees of freedom of all the particles in an area. And, when there is a loss of a region of space, the particles in that area will take their degrees of freedom with them. This creates a decrease in entropy density. So, entropy density is not the cause, but it is directly related to losses in the field of space. (I discuss this, along with many of the implications, in Marman, 2016, pp. 407-472).

To summarize, gravity resists being formulated as a quantum field theory because space is curved by abrupt first-person actions that disrupt fields. On the other hand, the dynamics of quantum states governed by wave functions are the result of second-person perception. All forces, except gravity, emerge from second-person exchanges. Every field is equally affected, but since they all follow the curvature of space, it looks as if they are dependent on the background of space.

4.9.2.10 Fewer Dimensions, Not More

It is now common to explore added dimensions, such as with super-symmetry and string theory, to uncover what is happening beneath the surface of reality, and to solve the problem of quantum gravity. The assumption behind all of this is that human beings can easily see and picture three spatial dimensions and one dimension for time, but we cannot see what is happening in higher dimensions directly. On the other hand, we can easily see what is happening in fewer dimensions, such as one or two dimensions of space, so there cannot be anything hiding there. Unfortunately, this assumption is only true when we look at dimensions through third-person lenses.

If the world evolves through sentience, then we need to consider perceptual dimensions. As soon as we do, we see that fewer dimensions *are* hidden to third-person lenses because outsiders cannot see first-person perceptions or the inner dynamics of second-person relationships. Therefore, the LoP Interpretation of QM suggests that not more dimensions, but fewer, need to be considered.

However, it is time to wrap up these speculations. With the above nine postulates, we are now ready to offer an explanation for why quantum formalism takes the form that it does.

5. Understanding Quantum Formalism

> The only consensual part of the [quantum] theory is a formal skeleton enabling one to calculate the probability of various experimental outcomes at any time, given the initial preparation. This formal skeleton is often complemented with bits and pieces of former pictures of the world borrowed from classical physics, but connected to one another in an unfamiliar and unruly way. A recurring complaint is that, as long as we are left without any truly coherent representation of the world and of its ‘ontological furniture’ compatible with the quantum formalism, we cannot claim that we truly ‘understand’ quantum mechanics. (Bitbol, 2010, pp. 54-55)

Why call this science quantum “mechanics” when there are no mechanical reactions – no cause-and-effect reactions at the quantum level? The reason is because there is one aspect of QM that is highly mechanical: quantum formalism itself. This is the mathematical process that physicists go through to determine statistical predictions. It has proven itself to be the single aspect of QM that physicists can depend on. No one has ever found a case where it has given a wrong answer. Therefore, the process of quantum formalism is seen as the true foundation of QM. And any new interpretation or theory must be tested by comparing it to the formalism.

This is why any formal interpretation of QM needs to explain what quantum formalism is trying to tell us. What does it mean? Why does the world work this way?

> Regarding its formal structure we could say that quantum mechanics seems to be a ‘finished theory.’ In terms of empirical adequacy, it provides outstanding results, its mathematical structure – developed in the first three decades of the 20th century by people like Werner Heisenberg, Pascual Jordan, Max Born, Erwin Schrödinger and Paul

> Dirac – seems able to provide until now the adequate modeling to any experiment we can think of. However, apart from its fantastic accuracy, even today its physical interpretation remains an open problem. In the standard formulation, quantum mechanics assigns a quantum mechanical state to a system, but 'the state' has a meaning only in terms of the outcomes of the measurements performed and not in terms of 'something' which one can coherently relate to physical reality. It is not at all clear, apart from measurement outcomes, what is the referent of this quantum state, in particular, and of the formal structure, in general. If we are to ask too many questions, problems start to pop up and simple answers seem doomed to inconsistency. (De Ronde, 2011, p. 9)

The Lenses of Perception Interpretation of Quantum Mechanics says that the reason it has been so hard to understand quantum formalism is because we have been trying to see it only through third-person lenses. There are no *observer-independent* quantum states. They do not exist. There is no valid *observer-independent* explanation for decoherence. As Smolin (2017) says, astrophysicists have come to the same conclusion about space: There is no *observer-independent* way of studying space or the universe. We can only study our universe from within the universe (pp. 17-26).

I believe this is what quantum formalism is trying to tell us: The foundation of reality is not built on a foundation of objective things and forces, but from dynamic relationships. Quantum states are relational, and this means we need a second-person lens to understand the "inner" dynamics between sentient agents.

We cannot understand organic life by studying it from the outside. As soon as we try to take an organism apart, we kill it. This is exactly the same message that quantum formalism tells us: The dynamic nature of quantum states comes from relationships that only exist between sentient agents.

If this interpretation is right, then everything that happens in QM relates to human relationships because we are sentient agents as well. This means that an intuitive understanding is possible that gives us a true and accurate description of quantum states and why they behave so strangely. As a result, the science of QM has a lot it can teach us about biology, sociology, and even psychology. Those sciences can also teach us valuable insights about QM as well.

Therefore, at a minimum, I need to show that the LoP Interpretation is consistent with quantum formalism. However, this seems like too low of a bar. What is really needed, as Rovelli said, is to show why the formalism takes the form that it does, from a set of basic postulates. But, there are quite a few questions raised by quantum formalism, as Matías Graffigna (2016) points out,

> [T]he primordial question should no longer be "how does nature decide the result of a measurement given a superposition?", but, rather, "what is a superposition and what can it do besides being actualized in a measurement?" It is not that the process of actualization through measurement were irrelevant or unimportant for QM, but it seems that some previous knowledge is necessary in order to tackle it. We do not yet fully understand what a superposition is, but we do have the formalism, and also the possibility of grounding this understanding in a different ontology from the one of classical Newtonian mechanics. (pp. 25-26)

Understanding what superpositions are is just one of the puzzle pieces we need to solve. There are many more questions embedded in the formalism that need to be answered.

There appear to be countless ways to present quantum formalism. They can all seem quite different at first. However, they eventually end up covering the same terrain. They just pick different places to start and take different paths to tie all the pieces together. I am going to follow an approach laid out by Albert (1992) because he focuses on what he calls the "algorithm," the mechanical process that gives quantum formalism the name of "mechanics." He says that "It pretty much all boils down to five principles" (p. 30). These principles represent the foundation of the formalism. However, a fair amount of added discussion is needed to understand these principles.

Following are the five principles, each summarized in my own words from Albert (1992, pp. 30-36), followed by explanations for why these principles are necessary elements of QM formalism:

5.1 Quantum States and Superpositions

> *Quantum states are represented by vectors called "state vectors." The state of every physical system is defined by a vector space that includes all of the possible states of the system, where each possible state corresponds to a vector and each vector has a length of 1 in that vector space. The vector space is complex (this means that both real and imaginary numbers are allowed). Each vector represents a quantum state, and all of the quantum states together represent the overall state of the system. Superpositions are represented by adding or subtracting state vectors using well-known vector math.*

From this first principle you can see the mechanical nature of quantum formalism. But to see how truly bewildering it is, we need to dig deeper. Bowman (2008) raises the questions to ask: What sort of information about a system do quantum states represent? Is all of the information about a system represented by its quantum states? And what exactly are quantum states? Then he explains that all of these questions are still unresolved after 80 years of debate (pp. 7-8).

However, there are quite a few things that physicists do know about quantum states. For example, they know that they are not the same as states in classical physics, where states represent the values of a system's properties, such as mass, electrical charge, momentum, location, etc. The trajectory of a system can be measured in classical physics, and, based on the forces acting on it, the future path of that system can be predicted with great accuracy (as long as it is a large object). Thus, a state in classical physics has numerical values that describes how fast the system is moving or the direction it is traveling, etc.

Quantum states, on the other hand, do not represent values. They represent functions. This means that quantum states cannot be represented by numbers because they are responsive states. The point is not that quantum states continually change, because states in classical physics also change. No, this is telling us that quantum states are dynamic functions. This is why they are often called wave functions, not waves.

To understand how abstract this idea of a quantum state is, look at how a force is represented by a vector in classical physics. The direction of the vector (where the arrow of the vector is aiming) represents the direction of the force. The magnitude of the force is represented by the length of the vector. This is easy to relate to. But what does a quantum state vector represent if it is a function?

Does the direction of a vector represent the direction of the function? No, not really, because it makes no sense to say that a function moves in a certain direction. Does the length of the vector represent the magnitude of the function? No, because in quantum formalism state vectors are assigned a length of 1.

This shows that quantum states are abstractions that are so far removed from classical states that they are not the same at all. Except for one thing:

Quantum states do contain essential information about every particle and system tested.

The problem is that this information is contained in a dynamic function and physicists do not know what a quantum state is. They cannot even agree on whether quantum states represent something real or if they are simply mathematical tools.

However, the postulates outlined in section 4 offer an explanation for what quantum states are and why we need to treat them the way we do in quantum formalism: Quantum states represent the inner dynamics of relationships between sentient agents. They are indeed dynamic functions.

The postulates also tell us that there are two different types of relationships: second-person and third-person. The inner dynamics of second-person relationships come from private shared perceptions that pass back and forth between those involved in personal relationships. Being private means that they are independent. Third-person relationships, however, are public and impersonal, which means that they are shared by every agent coupled to that field.

The first principle of quantum formalism, described above, is telling us that all of the relationships that a system is involved in have an influence on that system. This defines the state of that system.

All possibilities in second-person relationships act as superpositions because they all influence the system at the same time. And the reason you can assign all of these vectors a length of 1 is because second-person relationships are linearly independent of each other. This means that they influence each other, but only indirectly, because they are all vying to become actualized. However, only one possibility can be selected. As a result, only the phases between possibilities are important in determining actualized events. This is why adding and subtracting vectors offers an accurate way to represent the influence of superpositions, as long as the vectors are independent of each other.

It is easier to understand this if you think about the example I gave earlier: Imagine you have been given a new job offer, but the job requires moving to another country. This means that you might have to move away from the person you have been dating. This illustrates the influence of two *independent* relationships, where both weigh on you and your choices. Your job offer has no *direct* effect on your partner, except in how much that offer means to you. And your relationship with your partner has no *direct* effect on the job offer, except on how important your partner is to you.

If your partner wants to move with you to another country, then the phases between these two relationships add together. They complement each other. This option is easy to choose. But, if your partner has ties that hold him or her back from moving with you, then the phases between the two relationships subtract, forcing you to choose one or the other. Every relationship possibility that influences you and your partner adds to the complexity, and so does the timing. Thus, phases are a perfect way of representing how independent possibilities in relationships influence each other.

All second-person relationships are represented by complex vectors because they must have an imaginary dimension, according to the postulates I have presented. Mathematically, this dimension is represented by $\sqrt{-1}$, which shows that it is a private relationship and does not exist in the real world defined by third-person perception. Second-person relationships also need to include real dimensions if they are going to have an impact on the "world out there."

If you have a vector with a length of 1, and it is a complex vector (with both imaginary and real dimensions), then that vector will only have a length of 1 in real dimensions if it has no imaginary component. Therefore, as the influences of relationship possibilities evolve, we see the shadow of the line that falls on the real dimensions growing larger, and then shrinking, as the phases change. This shows how the phases of wave functions are represented by quantum formalism and why this math is a good way of representing the influence of the inner dynamics of relationships.

LoP theory says that third-person influences are different. They have no imaginary dimension. They are only real functions because they represent information that only belongs to the field of space. The field of space is our reference for everything that exists in the objective "real" world. This is why space always appears to be in the background, while all measurements and energetic events take place in the foreground.

This means that third-person relationships do not act as superpositions in relation to each other. This is what quantum formalism has been missing. And the reason this has been missed is because third-person relationships never offer possibilities that become actualized in measurements. They act only as "static" outside forces that have an inertial dampening effect on changes.

Quantum theory, as I said before, is *background-dependent*. This means that it cannot see changes to the field of space because it uses the background (the field of space) as its reference in every measurement. EM field effects, and particle fields, are accounted for in quantum formalism by using relativistic models, but this cannot account for what causes the field of space to curve. If LoP theory is valid, then Einstein was right that quantum theory is not complete. However, it becomes complete if we include the effects of first-person and second-person perception.

To summarize this first principle of quantum formalism: All of the quantum states of a system are the relationship possibilities influencing that system. However, this, alone, does not capture all of the information needed to determine the outcome. We must include first-person perception to explain the uncertainty and indeterminate nature of quantum states, the curvature of the field of space, and, as we will see below, the outcome of measurements.

However, looking only at the relationship possibilities, as this first principle of quantum formalism asks us to do, we can represent the state of any system by a vector space that is made up of all the relationship possibilities, with each second-person relationship needing a linearly independent imaginary dimension of its own, and where each vector has a length of 1. This describes exactly the special type of vector space that physicists use, called Hilbert space. Hilbert space is an *n*-dimensional vector space, where "*n*" represents each of the independent quantum states. Each independent state can be represented by dimensions that are orthogonal to each other, just like *x*, *y*, and *z* dimensions of 3-dimensional space are orthogonal, since quantum states are independent.

5.2 Observables: Measurable Properties

> *The measurable properties of a system, called "observables," are represented by linear operators that act on the vector space that is associated with the system. If a vector that represents a quantum state happens to be an "eigenvector" of an operator associated with a particular observable, and that eigenvector has an "eigenvalue" of "a," then the state is said to be an "eigenstate" of that observable. And, in this case, if a measurement is made, that state will have the value "a" for that observable.*

Once again, we see that this whole principle is a description of a mathematical process. It says that only some properties can be measured. Quantum states, for example, cannot be measured directly. But we can measure the location of a system or the momentum of a system.

In classical physics, we can obtain the momentum of an object by multiplying its mass times its velocity. Quantum states, however, do not have well-defined properties because they are functions. There is no way to determine the velocity of a quantum state because it is nothing more than a relationship possibility. The velocity of a relationship possibility does not even make sense.

Another problem with quantum mechanics is that we cannot measure both the momentum and the location of a quantum system at the same time because the momentum state and the location state are two different quantum states. This means that we need to use two very different relationships and two different types of equipment in order to measure them. This is represented mathematically by the use of two different mathematical "operators." Operators are mathematical functions.

Remember, a measurement, according to LoP theory (and the TI and RTI interpretations), requires an exchange of energy. And for this energy transaction to take place, both the emitter and absorber must both act in concert. This requires a second-person relationship between them, according to LoP theory.

This explains the meaning of this second principle. It is telling us that if a quantum state happens to be aligned with the measuring equipment, then that quantum state will be the state that defines the transaction. This means that the numerical value of that state will be the value that is measured.

For a quantum state to be "aligned" with the measuring equipment, it must be a vector that points in exactly the same direction (or the exact opposite direction) of the quantum state of the operator that represents the measuring equipment. This makes perfect sense because we already know that the emitter and absorber must have exactly the same wave function, except that the emitter wave function moves forward in time, while the absorber function moves backwards in time. Of course, they do not actually move through space-time, but the point here is that these two wave functions (quantum states) must be aligned exactly to couple together. This is what is needed to make the handshake that triggers the measurement event.

Whenever a quantum state is “aligned” with an operator that represents a specific observable (that represents the equipment used to measure that observable), then that quantum state is said to be an “eigenstate” of that observable. All that this is saying is that only a quantum state that has a vector that is aiming in exactly the same direction (or the exactly opposite direction) can be measured.

The reason this principle is important is because it tells us that when a quantum state is aligned with the measuring equipment, then if we make a measurement of a system, this aligned quantum state will dictate the value that we receive from our measurement. It also tells us that measurement affects the system. This is represented by the operator acting “on the vector space” of the system.

To picture what this means, imagine a two-slit experiment. The value measured will be indicated by the spot on the screen where the photon lands. This measurement result will be determined by the emitter-absorber relationship that becomes actualized. And that relationship can only become actualized if their wave functions are perfectly aligned with each other.

5.3 Wave Function Dynamics

> *Every quantum state changes and develops in a deterministic way, based on the forces and constraints acting on that state. There is a way to calculate what state that system will be in at a later time. The deterministic law that governs how a quantum state changes with time, for non-relativistic systems, is represented by the Schrödinger equation. Since every state vector must, by definition, be a vector of length one, and must remain a length of one as they change over time, the changes in state vectors dictated by the dynamical law are exclusively changes of direction, never of length. Thus, quantum states only change in a linear manner. This means that superposition states remain as superposition states, as they change over time.*

Note: Using the Schrödinger equation means that only non-relativistic quantum theory is involved. This means, first of all, that it only represents the emitter’s side of the story, not the absorber. And, secondly, it does not account for the creation and annihilation of quantum states.

What we see happening here is that quantum states evolve and change over time, but they do so only in a linear matter. This means that they never change suddenly and discontinuously. Since the creation and annihilation of quantum states are clearly cases of discontinuous change, the above description of how quantum states change is only valid when measurement is *not* involved.

Therefore, this principle of quantum formalism describes only the way quantum states change in “coherent” (unobserved) situations. In other words, relationship possibilities, by themselves, only *influence* other relationship possibilities through phase relationships (see 5.1). They cannot create discrete shifts or breaks. Thus, this process is not able to create a measurement transaction. Why is this process different from what happens during the process of measurement, which we will get to in principle 5, below? This is the question at the heart of “the measurement problem.”

As a result, this principle says that superposition states should never disappear. They should continue on forever. This is why we see the Many Worlds Interpretation, which suggests that each possibility becomes an actuality in a different universe. All of these problems go away with the LoP Interpretation (and with RTI – the Relativistic Transactional Interpretation as well).

It is also worth mentioning that the Schrödinger wave function describes quantum states as being spread out across space. The wave function represents statistical probabilities of where a system will be located over time. Remember, quantum particles jump around. They do not follow simple paths. The question remains, however, what is this “function” that is waving? Or is it purely a mathematical tool? This is a question that bothered physicist, John Bell, for most of his life:

> What is the Schrödinger wave function? The standard interpretation tells us that the wave function provides information about a quantum mechanical system, such as the probability that, when measured, “observables” have some particular value. But is this all we have – “information”? Isn't there something else behind the scenes? Bell used to conjecture that – while physicists, when they teach or even use the quantum theory, seem to accept the idea that all we have is information – in their heart of hearts they really believe that the wave function is not the whole story. The information contained in it refers to something else, something not revealed – a hidden reality. (as cited in Berkenstein, 2009, pp. 144-145)

The LoP Interpretation says that this hidden reality is composed of relationship possibilities. That is what the waves are made of. They change continually, just like waves, because they are shared states that evolve back and forth in dynamic ways between those involved. Quantum states (wave functions) spread across space because sentient agents are involved in relationships with other sentient agents. Quantum states are non-local because the dynamics of second-person relationships exist only between sentient agents, not in dimensions defined by the field of space.

This third principle stands as an important description of how relationship possibilities evolve over time when no measurement is taking place. And it fits perfectly with the LoP Interpretation.

5.4 Relationships with the Measuring Equipment and Born’s Rule

> *If a quantum state is not an “eigenstate” of the operator of an associated observable being measured (see 5.2 above), then, according to quantum mechanics, the outcome of such a measurement is a matter of probability. Born’s Rule stipulates that the probability of each measurement outcome will be the absolute square ($|a|^2$), if the value of that state is “a.” Also, any state that has a value of “-a” (which means the vector is pointing in exactly the opposite direction with the same length) will have precisely the same measurable outcome because $|a|^2 = |-a|^2$. Therefore, any vector with a value of “a” is considered precisely the same physical state as a vector with a value of “-a.” All measured values must be real numbers, and all eigenstate vectors of an observable must be orthogonal (at right angles) to each other.*

In 5.2, we saw what happens when a quantum state is already in a relationship alignment with the measuring equipment before the measurement takes place. The quantum state is then said to be an eigenstate of the operator (the operator represents the measuring equipment and the observable being measured). This is generally not the case in most experiments, unless the same measurement was performed shortly before.

This raises an interesting question: If no measurement was made previously, is there any way of knowing if a quantum state is an eigenstate of an operator, based on the results of the experiment? The answer is no. Therefore, the case sited in 5.2 only applies to repeated experiments – when the same measurement is run immediately after it had just been run (before the quantum state has been influenced by other forces or other measurements).

This fourth principle of quantum formalism applies to all other cases. This principle simply states that we must use Born's Rule (square the absolute value of the value of a quantum state), to find the probability that a state will become the actualized result of the measurement. Born's Rule is stated as a postulate, but, as we have already seen, the reason for squaring the value is because the emitter "offer" wave and the absorber "confirmation" wave must both be perfectly aligned in order to couple together. This is why we need to multiply them.

The square must be of the "absolute" value because these values are complex numbers. Remember, they can only be real numbers if they are fully aligned with the field of space. Only third-person relationship "confirmation waves" are aligned with the third-person field of space because they have no imaginary dimensions, according to the LoP model (see section 4.9.2.6). However, only second-person relationships are able to create measurement events. Second-person relationships always have an imaginary dimension because their inner dynamics are not visible to third-person lenses. If you square an imaginary number, you get a negative number. Using the "absolute" value means treating negative numbers as positive. In other words, it is the length of the vector that matters, not its direction, because probabilities must always be positive numbers.

This tells us that the "value" of a quantum state is directly related to the likelihood of it becoming actualized. According to LoP postulates, this value represents the "level of interest" for that relationship possibility shared by the sentient agents involved. This makes sense because the level of interest is directly related to the choices made by sentient agents. And, just as with probabilities, level of interest is always a positive factor. This is true even when agents find themselves opposed to each other – their level of opposition is still a positive factor. This is why some people become so obsessed with beating their adversaries that they forget about their family and friends.

This principle also says that any quantum state with a value of a is the same quantum state if it has a value of $-a$. This makes sense because when we use the relativistic model that includes both the story of the emitter and the absorber, we see that relationships and handshakes are only possible when both are exactly the same wave function, except one appears to move forward in time while the other moves backward. This means the two vectors are pointing in opposite directions. Thus, every second-person quantum state has a matching opposite state, because both are necessary to create a shared state.

This principle then says that all measured values must be real numbers. This is exactly how it must be, according to the LoP postulates, because all measurements are the result of a wave collapse, and a wave collapse is nothing more than an exchange of energy and momentum that changes a third-person field. All changes to third-person fields must be represented by real numbers because third-person fields are objective realities that act as our reference for real numbers.

The last point raised by this fourth principle is that all eigenstate vectors of an operator associated with an observable must be at right angles to each other. The reason for this is simple: because they are independent of each other. As Bowman says (2008): “Orthogonality implies linear independence” (p. 38). These quantum states must be independent because they represent second-person relationship possibilities. Such possibilities exist only between the agents in a relationship.

5.5 Wave Function Collapse

> *Measuring an observable changes the state vector of a system being tested, collapsing it, or making it jump from whatever state it was in before into an eigenvector of the measured observable operator. Which eigenvector is selected is determined by the probabilities outlined in the fourth principle (5.4) above. It is at this point, and no other point than this, that an element of pure chance enters into the evolution of the state vector. Once a measurement is carried out, the state of the measured system must guarantee that if that measurement is repeated immediately afterwards, the same result will be obtained.*

We now come to the act of measurement itself. This does not just apply to experiments with human observers. This principle applies to every exchange of energy – to every actualized event.

This last principle of quantum formalism tells us that the overall state of the system, which means all of the relationship possibilities that are influencing it from all of its relationships, goes through a discontinuous change when it is measured. This is sometimes called a quantum leap, because it suddenly leaps into a new state.

As we saw in 5.3, this process cannot be the result of the wave dynamics that govern the evolution of quantum states. This is the second missing puzzle piece in quantum formalism, because it cannot account for why the measurement process is different.

The Copenhagen Interpretation of quantum mechanics, which is the most widely accepted, says that this is a reflection of the statistical nature of reality. In other words, the reason one quantum state is selected over all the other possible states is based purely on its probability. This is the point that Einstein refused to accept. Einstein has been criticized over his comment that “God does not play with dice,” because many physicists think that he was simply unable to give up the old idea of classical physics. But that was not his objection. Here are Einstein’s actual words:

> Quantum mechanics is certainly imposing. But an inner voice tells me that it is not yet the real thing. The theory says a lot, but does not really bring us any closer to the secret of the ‘old one’. I, at any rate, am convinced that He is not playing at dice. (as cited in Born, M., 1971, p. 91)

If you cannot explain how a possibility is selected, then saying that quantum formalism is telling us that we live in a probabilistic world is meaningless. This is the point that I think Einstein was getting at. Quantum formalism does not tell us why probabilities govern the result of measurements in a statistical manner because the process that selects the outcome is hidden from third-person eyes. And if scientific equipment cannot see what is happening, then quantum formalism, which is nothing more than a formalism based on measurement results, tells us nothing about why or even how outcomes follow probabilistic laws.

The LoP Interpretation offers an intuitive answer: The possibilities of quantum states represent the influences of relationship possibilities. Which couples end up getting married? Clearly, those with the strongest level of interest in each other. But this is not always the case. Families have an influence. Some people meet and suddenly just decide to tie the knot on the spur of the moment. It is often surprising to see who decides to get married. Yes, statistically we can say that it follows their level of interest, but the fact is that we cannot know who one person will marry, or if they will marry at all. We cannot know because relationships are not simply the result of probabilities. Relationship possibilities are far more complex in the way they evolve.

Nonetheless, it is absolutely true that the moment a person marries all the other possible marriage opportunities vanish. Those possibilities disappear. Our lives *do* change when we get married. Our lives then suddenly start evolving and changing based on completely new possibilities. Thus, what this principle of quantum formalism is describing follows the LoP postulates perfectly.

The last point made in this principle of quantum formalism is that immediately after a measurement is made, if you measure the system again, you will get the same result. This also makes sense, because in the moment when an event becomes actualized, all of the other possibilities vanish. Over time, new possibilities will begin to emerge, but when you first find yourself in a new world, it takes time to get to know how to respond to that world.

The same is true with every major change of state. If you graduate from high school or college, or you join the military (whether by your choice or the government's choice), or retire, or when you go through puberty as a teenager, many of the possibilities in your life change at the same time. But it takes a while to see what this means. It takes time to relate to your new world.

This is why, after you measure a system, if you make the same measurement again, before it has a chance to evolve, you will find the same outcome. The reason for this is exactly what many physicists have said: It is because the superpositions have collapsed down to one actuality. The other relationship possibilities have disappeared, as they should if they are nothing more than possibilities.

This explains quantum formalism in an intuitive way, which is something that many have claimed is impossible. In fact, I believe it is clear that the postulates outlined in section 4 explain why quantum formalism takes the form that it does.

This, however, only brings us to the beginning. None of this is a conclusion or a proof. It only brings us to a starting point, where we have a new interpretation worth exploring. It needs further testing. It raises countless new questions. The implications are significant.

Fortunately, there are many ways to test this theory. It is not lacking in testability, as some other interpretations are. This will be explored briefly in the following section.

6. Challenges, Implications, and Opportunities for Testing

"The task is, not so much to see what no one has yet seen; but to think what nobody has yet thought, about that which everybody sees." This quote is often attributed to Erwin Schrödinger, but it was actually from the pen of Arthur Schopenhauer (as cited in O'Toole, 2015). After this quote, Schopenhauer continued by adding this: "For this reason, it takes much more to be a philosopher than a physicist."

When it comes to the interpretation of quantum mechanics, I would say that Schopenhauer is not quite right. The problem is not how to think about QM, but how to see it working in our everyday lives. As I said in another article, until we can do this, the revolution of QM will not be complete (Marman, 2016, April).

In order to see how quantum interactions work, we must add first-person and second-person lenses to the traditional third-person lens used in science. Each lens requires a different way of seeing, a challenge that is well-known to psychologists. Thus, in a strange way, to fully comprehend QM, if the LoP Interpretation is correct, we need to bring philosophy, physics, and psychology back together again. I say *again* because "natural philosopher" was the name for a scientist in Isaac Newton's day.

Trying to *think* about the problems of QM, in order to solve them, has obscured our way of seeing, because thinking "about" things uses third-person lenses. It starts with an assumption that we can solve these problems by looking at them from the outside. We cannot, because outsiders cannot see quantum states. Only those *involved* see the influence of relationship possibilities. Relationship dynamics are behind everything that happens in our daily lives and everything that happens in the universe. But we can only see this at the level of personal interactions. This is the quantum level.

The need to use added lenses is both the biggest opportunity for the LoP Interpretation and its biggest challenge, because learning to see through new lenses is not easy. To learn a new lens, we must set aside our normal way of looking at the world. It can feel confusing and uncomfortable switching to a new lens that is not familiar. It takes time for our unconscious to "catch it," but when it does, suddenly everything comes into focus, as we see clearly what the lens is showing us.

There are, however, quite a few other challenges. Too many to cover in this paper. For the last seven years, I have been looking for anything that might invalidate the LoP theory. I have studied physics, biology, psychology, neuroscience, and even some philosophy. I have found nothing that invalidates the premise of this paper. However, the following are the biggest challenges I have run across. They show where further research is needed and the opportunities they represent.

6.1 Hidden Variable Theories

When Einstein first began to question the implications of quantum entanglement, he wondered if there could be local hidden variables acting within entangled particles that caused them to behave as they did. The reason Einstein proposed this was because he could not see "action at a distance" as a possibility. No physical changes should be able to occur instantaneously across space.

In 1964, the physicist, John Bell, described an experiment that could determine whether it is possible for local hidden variables to produce the results of quantum entanglement.

Between 1981, when the first convincing test of Bell's Theorem was run, and 2015, when a test that closed all of the loopholes was completed, the results have shown convincingly that entanglement is a non-local phenomenon. These experiments have also been accepted as proof that local hidden variables cannot account for the behavior of quantum entanglement.

Since the LoP theory proposes that something within particles causes them to become entangled, the question can be raised: Is this simply a different type of local hidden variable theory? This is a good question, but the answer is no, for two reasons.

First, the postulates of perception show us that what happens within each particle is not enough to explain entanglement. In other words, first-person perception alone does not solve the problem. We need relationships to develop between particles. The dynamics of relationships do not exist in any one partner. They exist between partners. This means relationship dynamics are, by definition, non-local. In fact, this shows us the underlying reason why entanglement *is* non-local.

Second, the term "variable" has a specific meaning. It refers to a mechanism – a deterministic principle – that governs the outcome. This clearly is not what happens in relationships. There is no way to call relationships between sentient agents deterministic or mechanical. We never know exactly how they will turn out. Thus, the term "variable" does not apply either.

Physicists have taken the discussion about hidden variables in another direction, toward the question of realism. This is where it gets interesting. The current argument, as Gröblacher (2007) explains, is that the principle of realism is obeyed only if "external reality exists independent of observation" (p. 1).

Simon Gröblacher and his partners (2007) go on to show further that a broad class of *non-local* hidden variable theories fail to explain the results of quantum mechanics, as long as they hold onto traditional principles of realism.

> Most working scientists hold fast to the concept of 'realism' – a viewpoint according to which an external reality exists independent of observation. But quantum physics has shattered some of our cornerstone beliefs…. Here we show by both theory and experiment that a broad and rather reasonable class of such non-local realistic theories is incompatible with experimentally observable quantum correlations…. Our result suggests that giving up the concept of locality is not sufficient to be consistent with quantum experiments, unless certain intuitive features of realism are abandoned. (p. 1)

The point they make is that whether QM is local or non-local is less important. It is the principle of realism that matters the most. It is realism that is being put in doubt. They conclude their paper saying that any non-local extension of quantum theory, if it is right,

> has to be highly counterintuitive. For example,…consider the breakdown of other assumptions that are implicit in our reasoning.... These include Aristotelian logic, counterfactual definiteness, absence of actions into the past or a world that is not completely deterministic. We believe that our results lend strong support to the view that

> any future extension of quantum theory that is in agreement with experiments must abandon certain features of realistic descriptions. (p. 7)

This paper illustrates how deeply strange quantum states are and how far they take us from the traditional idea of realism. However, the results of the experiments described by the paper do not cast doubt on realism. They only cast doubt on the third-person idea of realism. It is our idea of what is real that needs to change.

The results of this paper, along with all the other tests of Bell's Theorem, are consistent with the LoP Interpretation (and with Kastner's RTI model as well). The problem with realism disappears once quantum states are seen as relationship possibilities. It is then valid to say that relationship possibilities *are* real because they *do* exist independent of observation by outsiders. However, they do not exist in space-time. They exist only between the sentient agents involved.

Let's go through the list of realism features that the above paper says we must abandon. I have already shown that relationship possibilities defy Aristotelian logic in section 4.6, such as the Principle of Non-Contradiction and the Law of the Excluded Middle.

Now look at the next principle mentioned above: "counterfactual definiteness." This means that if something is real, it must exist even when it is not being measured. Is this true for quantum states? Yes, because they *do* exist, but not in space-time. This is exactly what it means to "take Heisenberg's potentia seriously." Relationship possibilities *do* exist, and they *do* affect us.

The next principle of realism that the paper says we must abandon is "absence of actions into the past," meaning that it should not be possible for us to influence the past from the future. I have shown how this is exactly what *appears* to happen in delayed quantum eraser experiments (see section 4.9.2.4). However, this illusion is easily explained once we realize that entanglement is a shared quantum state that exists outside of space-time. Therefore, there is no causation backwards in time. In fact, this has nothing to do with causation or "action" at a distance because it is only the quantum wave functions that are changing. Einstein was right: All true action – all exchanges of energy – must be local because they are space-time events, as we saw in section 4.9.

Lastly, the paper says that we must give up on a "world that is not completely deterministic." Many physicists are still not willing to accept this. However, when it comes to relationship possibilities, it is clear that they are *not* deterministic. We know this from our own day-to-day lives.

Therefore, we can state unequivocally that quantum states are "real" because they *do* exist independent of outside observation. Thus, realism survives. It only seems counterintuitive if we keep trying to look at the world *only* through third-person lenses. The moment you put on a pair of second-person goggles and look at quantum states as relationships, then quantum behavior makes perfect sense. Thus, Einstein's intuition was correct.

We know that relationship possibilities play significant roles in our lives. People who use third-person lenses to judge relationships based only on what they are now and refuse to consider the possibilities of what they can become are sentencing those relationships to death. Possibilities give our relationships life. Thus, there is no reason to cast doubt on the realism of quantum states.

6.2 The Combination Problem of Panpsychism

I will let the philosopher of consciousness, David Chalmers (2017), outline the problem here. It should be easy to see that this represents a serious challenge for the LoP Interpretation:

> Panpsychism, the view that fundamental physical entities have conscious experiences, is an exciting and promising view for addressing the mind–body problem. I have argued in “Panpsychism and Panprotopsychism” that it promises to share the advantages of both materialism and dualism and the disadvantages of neither. In particular, it can respect both the epistemological intuitions that motivate dualism and the causal intuitions that motivate physicalism.
>
> Nevertheless, panpsychism is subject to a major challenge: the combination problem. This is roughly the question: how do the experiences of fundamental physical entities such as quarks and photons combine to yield the familiar sort of human conscious experience that we know and love. (p. 1)

Chalmers breaks the combination problem down into three parts, based on three different aspects of conscious experience: First, the subjective nature of conscious experience because it belongs to a subject – the one who is having the experience. Second, the qualitative nature of conscious experience because experiences are composed of subjective qualities that combine together. Third, the structural nature of conscious experience because our experiences of the world have a complex materialistic structure that seems inconsistent with our subjective perception. Here is a summary of the three combination problems, in my words, from Chalmers’ paper (pp. 4-6):

1. **The Subject Combination Problem:** How do micro-subjects, such as sentient quarks and photons that have conscious experiences (which means that they are subjects) combine to make macro-subjects, such as cells and living organisms, which are also sentient?

2. **The Quality Combination Problem:** How do micro-qualities, such as the experiential quality of redness, that we feel when seeing something red, form macro-qualities, such as when many micro-qualities come together to create our singular experience of a sunset?

3. **The Structure Combination Problem:** How do micro-experiential structures and micro-physical structures combine to create macro-experiential structures? For example, why does the macro-physical structure that we call a “brain” seem completely different from our experience of having a brain?

Chalmers adds an important note about these three problems. He writes:

> It is common for a proposed solution to the combination problem to address only one of these problems: most often the subject combination problem and occasionally the quality combination problem. It should be stressed that a satisfactory solution to the combination problem must address all of these problems. This raises the bar for a solution, as it is far from clear that any single proposal can solve all the problems at once. (p. 6)

The LoP Interpretation is able to offer a solution to all three of the combination problems. That is good news. And it leads to a simple, intuitive way of putting the three combination problems in perspective, which is also good news. For example, the LoP theory suggests that problem 1, the subject combination problem, is about first-person perception and the *impossibility* of combining first-person perception. Problem 2, the quality combination problem, on the other hand, is centered on the nature of second-person experiences and how they *do* combine. And problem 3, the structure combination problem, is about how third-person perceptions combine and why they are different.

This need for all three of the fundamental lenses of perception suggests that the LoP Interpretation is well-suited to understanding the combination problems of panpsychism. However, in order to resolve the underlying issue of problem 1, the postulates of section 4 lead to a truly surprising solution that goes against common wisdom. This presents us with another major way to test the validity of the LoP postulates. This is a significant challenge facing the LoP Interpretation. Let's take a look.

6.2.1 The Nested Structure of Living Creatures

Let me begin by describing how the underlying issue of problem 1 hit me, some five or six years before Chalmers published his paper. I had already worked out the nine postulates of section 4. However, as I was studying the way these principles apply to living organisms, I noticed something important was missing.

The postulates listed in section 4 describe two fundamental types of relationships: second-person and third-person. The problem is that neither of them seem capable of creating the nested quality that we see everywhere in nature. This struck me when looking at the biology of the human body. We see cells working together so closely that they act as one functioning body. At the same time, within each cell, we see molecules and genes working together to keep each cell alive, so that cells are able to act as sentient agents.

As I have shown in section 4.9, second-person relationships are not always equal, because energy flows from a higher potential to a lower potential to create a wave collapse. We see the same thing with dance partners. They work best when one starts off leading and the other follows. However, as partners get to know each other, the gap between leading and following tends to become fluid and often shifts back and forth. What matters is that the back-and-forth alignment continues, as partners move with each other in a responsive way. This is where wave functions come from. However, I could see no way for nestedness to arise from these one-on-one relationships.

Third-person relationships create backgrounds, such as societies or cultures. They create a sense of what is normal in a way that applies pressure on agents who go against the norm. Thus, I could not see how third-person relationships could ever create the nested nature of living organisms.

It is possible, of course, that this nested quality that we see in biological organisms might only be a macro-level property. It might have nothing to do with quantum principles. After all, creatures have far more degrees of freedom than quanta, so it might not even be possible at the level of fundamental particles. However, if the LoP theory is valid, it should offer some explanation for how nestedness emerges. So, I went back to the postulates of perception. Is this something new, or can it be explained with LoP postulates? The answer was simpler than I expected.

As I looked closer at multicellular organisms and asked myself why cells work for an organism, I began to see that cells truly dedicate their lives to something larger than themselves, and they work so closely together that they act as one body. Considering this from a cell's point of view, I noticed that each cell seems to be entangled with the organism it belongs to. And animals and plants also depend completely on their cells to live. Organisms act as if they are inseparable from their bodies. Equally, the fate of their cells depends on the survival of their host. This struck me. It looked like a shared quantum state of some kind between sentient agents in a nested structure.

With second-person relationships, a shared state is formed when two agents perceive that they share an interest in each other and they both reinforce it. Is it possible that all the cells in our bodies share a common interest together?

According to the postulates of section 4, second-person relationships between cells are not enough to form bodies, they will only lead to attraction or repulsion between pairs, and exchanges of energy, as we see with electromagnetism. That is when it hit me; nesting is something different. Cells in an animal's body are not just involved in relationships with each other. They are also entangled with the animal itself. In other words, each cell forms a one-on-one relationship with the "being" who inhabits the body. That appears to describe what is happening. Can this be right?

It turns out that this is fully consistent with the postulates in section 4. For example, first-person perception always belongs to someone. This means that the first-person perception of the organism cannot be created by the cells. Secondly, entanglement is only possible between sentient agents.

As soon as I realized this, I saw something else: The distinction between the cells and the "being" who inhabits the body is black and white, because the cells of the body and the sentient agent who inhabits the body work at two different levels in the nest. This distinction is as black and white as photons in a spin-up or spin-down state, or electrons leaping from one energy shell to another in an atom. LoP postulates say that this black-and-white distinction should maximize the strength of their entanglement.

Differences between the cells in multicellular organisms, on the other hand, are not distinct because they are clones of each other. Their differences are grey, especially when embryos first start to develop. However, the being who inhabits a body works at a higher level than the cells. This should make the bond maximally strong. And this bond should significantly increase the entanglement between the cells as well, because the cells share this quantum state together with the being who inhabits the body. This does seem to describe why cells work as a unit for the sake of an organism.

I call this an "all-for-one" relationship, after the famous quote from The Three Musketeers who worked as a team for the sake of king and country: "All-for-one and one-for-all." This is clearly something that we experience as human beings when we join teams working for a higher purpose. We feel the added sense of empowerment that comes from working for a shared goal, especially when the goal is meaningful. This is indeed a different bond than one-on-one relationships.

However, this is where the Combination Problem raises its head, because the Three Musketeers did *not* create a new living entity by working together. Yes, the king does work at a different level in a hierarchy, so we do see some of the same traits of nestedness here, but the king is just another human being, and a “country” is not a sentient being.

When I looked closer at the details about how the postulates of perception apply, it became clear that, if this all-for-one relationship does exist as a quantum state, then we should see two types of all-for-one relationships: A strong bond should exist when the outer level of a nest is a sentient agent. And a key characteristic of this strong bond is that when the outer agent dies, so does its body. The cells cannot hold together for long after their shared purpose disappears.

A weak type of all-for-one relationship, on the other hand, should emerge when one sentient agent steps forward to lead a group. This bond is weaker because the only distinction between that one sentient agent and the others is that it is acting as a leader. This should never create a state of full entanglement because other agents can easily step forward to take over as leader. However, this weak bond plays a role that is just as important: It creates organizational structures that can survive for generations – longer than the lifetimes of any of the agents themselves.

Biologists do indeed see both of these types of nestedness in nature. This is a good sign. But, if this is truly a shared quantum state, then we must see the same pattern of behavior at the level of quanta as well. This is where the added constraints of the LoP Interpretation kick in. If all-for-one relationships are formed by a combination of second-person relationships at the organism level, then we should be able to find the same thing happening at the level of fundamental particles.

We do. The “strong force” of physics is activated when three quarks work so closely together as a group that they act as a single entity. This is how protons and neutrons are created. Protons and neutrons also bond together through the strong force to form the nuclei of atoms. We see this same trait of nesting at the quantum level.

This was my first test of this new conjecture about all-for-one relationships. I then studied the problem closer and was surprised to see how well it describes the “strong force.” The Standard Model of Particle Physics uses quantum field theory to explain how the strong force works. This is a relativistic model, which means that the strong force arises when virtual quanta are exchanged between particles, as we saw previously with the EM force (see section 4.9.1). In the case of the strong force, however, three quarks join together to trigger the strong force reaction.

All three quarks must come together at the same time. And each quark must carry a different “color” charge, and all three color charges must complement each other in a precise way that activates the bond. These “color” charges have nothing to do with visual colors. In fact, they cannot be seen or detected directly. The three charges are named “red,” “green,” and “blue” because, when you combine red, green, and blue light, they make white. In other words, “color charges” are only used to symbolize the invisible exchange between quarks and how all three need to come together to activate the strong force.

The moment the strong force activates, a new “baryon” particle is created, such as a proton or a neutron. And, because protons and neutrons both clearly act as if they are individual agents, we know that this is a *strong* all-for-one relationship. However, this gives us a truly bizarre way of looking at protons and neutrons because it suggests that sentient agents inhabit the bodies of protons and neutrons, just like we, as human beings, inhabit our bodies. Is this possible?

To pass this test, I needed to make sure that it aligns with all of the known properties of protons and neutrons. And the principles of the strong force must equally apply to organisms as well. This is a high bar. As far as I can see, it passes this bar. Let's take a brief look.

The fact that each quark must have a distinctly different charge makes sense because this enables strong entanglement between the quarks. This reveals an interesting aspect of all-for-one bonds that I did not notice at first with organisms. However, it explains why cells naturally differentiate and specialize from each other when an embryo develops – it makes the all-for-one bond stronger because it makes the entanglement between them stronger. In other words, diversity plays an important role in creating stronger teams. A team is more effective when each individual takes on a specialized role and those roles complement each other. This is the same way that color charges act with the strong force.

According to quantum field theory and Kastner's RTI model, three one-on-one relationships form between the quarks. For example, if the quarks are named A, B, and C, then the three relationships are: A-B, A-C, and B-C. And, between each of these pairs, "gluons" are emitted and absorbed. Gluons are force carriers for the strong force, just like photons are carriers of the EM force. So we see similar relationships to emitters and absorbers in electromagnetism, where virtual photons are emitted and absorbed, creating attraction or repulsion. However, with the strong force, a far more powerful attractive force emerges, but only when all three quarks align with each other in a shared state. Then, not only do the three quarks form attractions with each other, but so do the red, green, and blue gluons. This truly describes an "all-for-one and one-for-all" state. Remember, the strong force does not exist before it activates, and it only activates when three quarks unite.

The only thing that is missing, according to LoP theory, is the sentient agent who inhabits the proton. This should be no surprise because sentient agents are not visible to outsiders. We only see their bodies, not the agents themselves. The only visible evidence of sentient agents comes from seeing how they act as responsive individuals. This is an indication that internal agents are present. The fact that protons and neutrons act as singular particles is consistent with this. Indeed, protons and neutrons act as distinct individual particles in all of their interactions with other particles.

This describes a remarkable similarity between living organisms and quantum relationships. We can add it to the list that I started in section 1. However, this similarity may be the most surprising of all. The way quarks form protons and neutrons, and the way those protons and neutrons form atoms, displays the same property of nesting that we see between life forms in nature. And this also explains how communities, families, countries, and companies are formed, when people work together for common goals.

However, if our model is going to survive, it needs to pass a second test as well: We must see *weak* forms of all-for-one relationships at the quantum level as well. We do. This is truly surprising.

The exact same combination of quarks and gluons that create a proton (two "up" quarks, one "down" quark, one "red" gluon, one "green" gluon, and one "blue" gluon), combine to create another particle as well: the "delta+" particle. And the bond that holds the delta+ particle together is exactly what we would expect – extremely weak – because there is no sentient agent inhabiting the particle. One of the quarks simply steps forward to act as the leader. While the lifetime of a proton is so long that it has not yet been measured, delta+ particles quickly fall apart. They decay in less than a millionth of a second. Measurements show that the binding force holding the quarks together in delta+ particles is much weaker than in protons.

This is of course a speculative proposal, but the remarkable resemblance here between quanta and living organisms, once again, is breathtaking. More testing is clearly needed, especially because the Standard Model of Particle Physics says that the strong force cannot extend beyond the nucleus of atoms. This idea that the strong force could be involved in the relationship between organisms and their cells goes completely against common wisdom. Fortunately, this speculative theory leads to a number of surprising predictions that are confirmed by evidence, as I explain in my book (2016, pp. 248-270), and as we will see in some examples below. This adds more weight. But more validation and scrutiny is clearly needed for something this controversial.

Comparing protons to a living cell seems outrageous, until we see the remarkable similarities. For example, the biggest mystery about living cells is what makes them alive. How do all those highly *specialized* and different molecules keep the flow of energy moving within the cell? Biologists have not solved this problem. However, the energy that comes from quarks working together is quite similar.

In fact, the energy produced by the strong force in protons is so strong that it gives protons one hundred times more mass. In other words, if you add the mass of all the particles together inside the proton, they only add up to one percent of the mass of the proton. The rest of the mass comes from the energy that moves the quarks to spin as one unit, and the binding energy that pulls the quarks together.

The fact that quarks in a proton spin as one is another unsolved problem of physics. It is called the "proton spin crisis" (see Jaffe, 1995, and Hetherton, 2015). Yet, this flow of energy never stops inside of a proton, as long as that proton survives. This is similar to the flow of energy in cells.

I am now writing a paper, with the help of biologist Alan Rayner to explain in more detail how energy keeps flowing in cells. The nesting relationship between quarks and protons offers a bridge between the formation of atoms and the formation of cells that may also explain how the first cells emerged. This gives us a possible new way of looking at what it is that makes organisms alive and how cellular life began.

After seeing how well all-for-one relationships seem to describe behaviors at the quantum level and the level of organisms, I believe these relationships offer a viable solution to the first of the three combination problems. It does not tell us where "beings" come from when they are born into a body, or where they go when they die, but those are not new questions. However, it does tell us that the first-person perception of an organism is not made from a combination of cells. Sentient agents are not created from relationships any more than consciousness is created by the interactions of neurons. The opposite appears to be true: Sentient agents are needed *first* to create dynamic relationships.

Actually, the LoP theory can offer a scientific explanation of sorts for where sentient agents come from when "born" into a body: They come from the same place that virtual photons come from before crossing over to become real photons. They come from that same reality where first-person perception exists, even though it cannot be seen by outsiders. They come from the same place as the "imaginary" mathematical dimension where quantum states exist independent of observation.

The fact is that beings are always invisible because outsiders cannot see first-person perception. We only see sentient agents by their responsiveness – by what they *do* with matter and energy. We never see the agents themselves. This is why I said above that the subject combination problem is all about first-person perception. All-for-one relationships play crucial roles, but they are, after all, simply another type of relationship that sentient agents naturally form with each other.

6.2.2 The Unconscious Formation of New Lenses of Perception

The quality combination problem is about the way we unconsciously form new ways of relating. This describes what happens when we form new working lenses of perception.

I gave examples of this in section 3.3.2, when a child learns to walk on their hands or skate on ice. The child learns by trial and error until they finally get the hang of it. That is how they learn a new working lens of perception. As a result, they can walk on their hands without being able to explain how they do it. This is because learning a new skill is an unconscious process.

Babies learn to walk and talk through the same unconscious process, and how to distinguish their body from the rest of the world. One day they simply know how to do these things. Countless feelings and sensations come together to form a single meaningful way of relating to their body. This is how babies "get to know" their bodies. It is the same way we get to know another person by forming a relationship with them. We get to know them unconsciously by doing things together, talking with them, and laughing at each other's jokes. This is how we learn through experience.

This describes the unconscious process we go through to learn how to relate to others. We use the same approach in learning how to relate to situations and environments. And we need to learn a new working lens for how to raise children. This explains why we act and feel different when we are with our children compared to how we feel and act at work, or how we feel and act at a concert surrounded by hundreds of people we do not know.

Each situation brings countless feelings and sensations together into a singular experience because we have a working lens that shows us how everything fits together. We get to know those situations like a friend. This is what it means to form a new lens. We automatically and unconsciously switch lenses when we leave our family in the morning and go to work. We switch gears because each situation needs a different way of relating. Our personality and sense of self actually changes. This happens because our unconscious sees the whole situation as if it were a person. Our unconscious works this way because it uses the second-person lens to relate to everything.

Second-person perception begins with half-formed perceptions and emotions. These are superpositions that hit us all at the same time until it becomes clear how to relate to a situation.

Then, only when it becomes clear to us, we are able to act consciously. This is why quantum states form first before action is possible. Relationship dynamics must always develop first.

I believe this offers a way of explaining the quality combination problem. Seeing a sunset means something to us because it is more than just an amalgam of sensations. The sight of the sun sinking below the horizon, which is something that has happened for billions of years, connects us to something timeless: The end of another day. We experience the stillness between day and night, as we switch from one lens to another. We do, in a sense, make a change within ourselves when switching from day mode to night mode. This makes sunsets a moving experience. Without even thinking about it, the feeling is special.

6.2.3 The Outsider Experience

Why does seeing a brain with our eyes, or studying a brain scientifically, seem so different from the experience of living in a body with a brain? This is the structure combination problem. I believe this problem is all about why third-person perception is so different from first-person and second-person perceptions.

The "outsider" perspective has grown over the last few centuries. It dominates our modern world because science and technology has changed our lives so dramatically. Hundreds of years ago, people felt much more involved in their personal experience of life. However, if you go back thousands of years, or look at the lives of indigenous people, we know that they see themselves as a part of nature, not separate from the habitat they live in.

Third-person lenses are not able to see quantum states, the dynamics hidden in relationships, or first-person perception. This is why, when neuroscientists study the brain, they only see a piece of meat with no sign of the consciousness that is able to experience a sunset.

The use of third-person lenses has grown because it is the best lens for studying cause and effect. Thus, it has become a great tool for discovering scientific truth. Much of the macroscopic world can indeed be explained by forces acting on objects, and we can easily study these reactions as outsiders. However, each lens is limited. A lens is simply a way of seeing – a way of relating. Each lens forms unconsciously through experience.

We do experience the "outside" world, and we can indeed relate to outside forces because third-person fields play an important role in our universe. However, if we try to use third-person lenses to study relationships, we interfere with the spontaneous flow. This is why the scientific lens has not yet found a way to explain what it is that makes organisms alive. And if we try to objectively study ourselves – analyzing our first-person perception as outsiders – we see no sign of self.

If quantum behavior is indeed the result of relationship possibilities, then we must learn to set aside our outsider perspective if we want to grasp the meaning of what quantum mechanics is trying to teach us.

Our use of third-person lenses has taken us far. It has transformed our world. But we have hit a wall when it comes to understanding how everything works at the level of individual agents. In other words, how everything *really* works when you look closely. We cannot see what is happening before our own eyes if we insist on using the wrong lenses.

Our experience of living in a body with a brain is a first-person experience. We have learned how to use our body and brain through working relationships. We cannot explain how we actually move our muscles because our cells do the actual work through all-for-one relationships, but we do lead our cells, and they follow our lead when we decide to act, because our life is their life. We are in this together. This is what it means to live in a body. All-for-one relationships allow us to move our bodies as a single individual. However, our bodies are in fact legions of cells and helpful bacteria working together.

In other words, third-person lenses never see what is truly happening beneath the surface, even when it comes to purely mechanical reactions. The discovery of quantum mechanics is a door that leads to a new understanding of reality. We just need to "get to know it" like a friend and see the meaning of relationship possibilities. Analyzing it as an outsider is not enough.

That is the lesson of QM, if the LoP Interpretation is right. And it shows a possible solution to all three of the combination problems. The LoP postulates show us why we need three fundamentally different lenses. And once we use all three, all of the combination problems seem to be resolved.

Of course, this is just a brief look at these issues. A more thorough investigation is needed. There are many opportunities here to test the LoP Interpretation.

6.3 The Five Unsolved Problems of Physics

In the spirit of revealing the biggest challenges facing the LoP Interpretation, I need to include something physicist Lee Smolin (2007) wrote:

> The core of our failure to complete the present scientific revolution consists of five problems, each famously intractable. These problems confronted us when I began my study of physics in the 1970s, and while we have learned a lot about them in the last three decades, they remain unsolved. One way or another, any proposed theory of fundamental physics must solve these five problems. (pp. 3-4)
>
> These five problems represent the boundaries to present knowledge. They are what keep theoretical physicists up at night. Together they drive most current work on the frontiers of theoretical physics.
>
> Any theory that claims to be a fundamental theory of nature must answer each one of them. (pp. 16-17)

I took this challenge seriously. Before publishing anything about the postulates of perception that I had developed, I wanted to see if the LoP Interpretation could offer at least some form of solution to "The Five Unsolved Problems of Physics." It took me years to work through these five problems. I finally found a way to answer each of the problems (as I show in Marman, 2016, pp. 407-473). However, these answers should all be seen as speculations in serious need of validation.

The fact that postulates of perception can offer a way to make sense of these problems increased my confidence in the LoP Interpretation. However, more scrutiny is clearly needed.

Let's take a look at the five unsolved problems. These are very brief summaries that hardly do justice to the explanations behind them, or the experiments that support these proposals. Further information is available in the footnotes to each problem:

6.3.1 Problem One: Offer a Single Theory that Explains Both General Relativity and Quantum Mechanics.

The principle of relativity itself derives from first-person perception. All measurements are relative because all transactions of energy require first-person perceptions to collapse the wave function. This is why everything that happens is relative. QM, on the other hand, is all about second-person relationships. Thus, relativity and QM originate from two different lenses. Perception is the single underlying principle that ties them together.

However, the real issue created by the gap between relativity and QM is the problem of "quantum gravity": Why is it so hard to make gravity work with quantum field theory? This requires showing how gravity emerges from the behavior of quanta. Since I have discussed this in sections 4.8 and 4.9, I am offering only a brief summary here:

The story of gravity begins with the formation of the field of space. All the particles in our universe belong to this third-person field. It forms through the process I explained in section 4.8. However, every exchange of energy creates a shift in perception that disturbs the field of space (see section 4.9). The reason this happens is because the field of space is a public reality held together by the reinforcement of outsider perceptions. When energetic events happen, the public field must adapt. The field of space warps, as it adjusts to the changes created by wave-function collapses.

Gravity is a problem for quantum field theory because the wave function collapse is not explained by quantum formalism. We need a relativistic quantum theory to see the way that quantum states are created and annihilated. According to LoP theory, fields are not the causes of these events. Fields only adapt to them. The actual cause of gravity ties back to first-person perception. Both an emitter and absorber must work in concert to make a transaction of energy happen. Energy density is proportional to the force of gravity because energy transactions are proportional to energy density. Energy transactions are the true cause behind warps in the field of space.

An energetic event temporarily disrupts the field of space, causing some of the particles closest to the wave collapse to lose their connection with the field of space. The loss of these particles is short-lived because they soon rejoin the field of space. However, with a continual series of wave collapses, the field itself warps as it continually tries to fill the void. As a result, there is a drop in the entropy density in that region. This is why recent research has proposed that entropy density may explain the emergence of gravity.[7]

6.3.2 Problem Two: Resolve the Troubles of Quantum Mechanics, Either by Making Sense of the Theory, or by Inventing a New Theory that Gives a Deeper Understanding of Nature.

LoP theory shows that quantum behavior is the result of the hidden dynamics in relationships between sentient beings. These hidden dynamics come from the possibilities that weigh on sentient agents in relationships. Thus, Heisenberg's "potentia" should be treated as something real.

---

[7] See details in Marman (2016, pp. 411-429).

Relationship possibilities are peculiar because they do not exist in space-time. That is why they are hidden from outsiders and from third-person perception. Quantum mechanics cannot explain why the wave function collapses or where particles and quanta come from until we include first-person and second-person perception. Adding those two lenses completes the picture.

To illustrate the power of this solution in my book,[8] I show how it resolves problems that physicists are struggling to understand, related to the nature of particles, and why particles act so weird at the quantum level. The answer is simple: Particles are not bits of matter; they are sentient agents. That is why they behave like individuals, not like chunks of matter in specific locations of space.

6.3.3 Problem Three: Can All Four of the Forces of Physics and All the Known Particles Derive from a Single Source?

LoP theory says that particles exist because sentient agents are responsive and receptive in how they relate to each other. The properties of matter-type particles come from particle fields that those particles belong to. For example, a particle cannot exist as an electron unless it belongs to the electron particle field. The properties of force-carrying particles, on the other hand, are defined by the relationships they are exchanging energy for. This offers an explanation for why photons and gluons are massless particles, while matter-type particles have mass.[9]

Forces, however, emerge from relationships. Each of the four forces are created by a different relationship: Electromagnetism is the result of one-on-one relationships. The strong force comes from all-for-one bonds. The weak nuclear force comes from relationships that particles have with particle fields. And gravity comes from joint first-person actions that warp the field of space.[10]

In the process of trying to solve Problem Three, I made an even more surprising discovery: LoP theory predicts that there should be six forces, not four. It says there should be two additional forces, but no others.

It turns out that both of these new forces are well supported by empirical science. They both describe phenomena that physicists are well aware of but have been unable to explain: The first added force is dark energy (see the explanation for this under Problem Five, below). The second force explains the strange practice of *renormalization* that physicists have been compelled to adopt, where matter-type particles are treated as if they are surrounded by clouds of virtual particles. Electrons, quarks, and neutrinos are all surrounded by virtual particles due to all-for-one relationships with those virtual particles. These virtual particles actually form the bodies of the electrons, quarks and neutrinos. Experiments have proven the validity of this model.[11]

---

[8] Marman, pp. 429-433.
[9] Marman, p. 445.
[10] Marman, pp. 433-465.
[11] Marman, pp. 462-465.

If LoP theory is right about where forces come from, then these added two forces must also exist. The fact that these two forces have already been detected provides a bit of nice validation.

6.3.4 Problem Four: How Are the Values of Constants Chosen in Nature?

LoP theory shows how the constants of nature emerge from relationships, but the answer is not what physicists were hoping for. They would like to find an equation that predicts the values of all constants. However, if the LoP Interpretation is right, there is no such formula, since the process of "spontaneous symmetry breaking" that creates the values of these constants is determined by choices made in relationships. The fixed nature of these constants, such as the mass of electrons and quarks, comes from third-person fields. LoP theory suggests that these values evolved over time – they were not always the same as they are today.[12]

6.3.5 Problem Five: Explain Dark Energy and Dark Matter. If They Do Not Exist, Why Does Gravity Act So Strangely on Large Scales?

Dark energy emerges as a new force from the way the field of space forms. This new force not only describes the properties of dark energy accurately; it shows that it should act like a "cosmological constant" as proposed by Einstein, which means that space should expand equally everywhere. To put it simply, dark energy comes from new particles that enter and join the field of space. Those particles originate from a virtual state. Virtual particles continually try to join our universe, but most are unable to pass the threshold of perception needed to join the field of space. In the rare cases when new particles do join our world, space everywhere expands.[13]

Space is not expanding due to the force of a big bang explosion. It is expanding because new particles continue to join the field of space. This is why the overall field of space remains flat.

The acceleration of this expansion is slowing down because, as the universe grows larger, it is more difficult for particles to join the field of space. It is more difficult because the threshold of perception needed to join a field is determined by how many members it has. Small fields are easy to join, which is why the universe grew so rapidly at first. Thresholds of perception play important roles with second-person and third-person relationships, and thus all of the forces as well. These thresholds also determine which forces will take priority.

Dark energy is a straightforward consequence of the LoP principles of perception. In fact, LoP theory cannot avoid it. If the LoP theory of gravity is right, then the dark energy force must also exist as a distinct force.

Dark matter is a different story. It is not a new force. It is a display of an already known force: the "strong force." This is admittedly one of the strangest outcomes of the LoP model. It is directly related to all-for-one relationships and offers another way to test the LoP postulates of perception.

According to physicists, the strong force only works in the subatomic domain. However, the LoP Interpretation says that this force is caused by a group of quarks coming together to form protons and neutrons that are bodies inhabited by sentient agents. This is why protons and neutrons act as individuals.

---

[12] Marman, pp. 465-467.

[13] Marman, pp. 467-471.

LoP postulates predict that this should happen at every level where sentient agents form group relationships. If this is true, then we should also see the same behavior in stars and galaxies, if, and only if, stars and galaxies are also the bodies of sentient agents. This is a deeply divergent idea that clearly goes against common wisdom. However, it describes the behavior of dark matter so much better than any other theory that it deserves a chance to be reviewed. Let me explain.

Physicists know that about 98 percent of the mass of an atom comes from the strong force. Less than two percent comes from the protons, neutrons and electrons that make up the atom. In other words, 98 percent of the mass inside an atom is “dark” because this mass is invisible when seen from the inside. Atoms have this added mass for one reason: They resist outer forces as a unified body. In other words, atoms act and move as individuals. Therefore, 98 percent of the mass of an atom comes from the strong force energy that binds atoms together. Physicists agree with this.

Inside the atom, this added mass is invisible – it is dark. According to LoP, the dark mass in galaxies comes from this same bond. Gravity is not the only force holding galaxies together.

This explains why physicists have found no trace of dark matter particles or measured any effects of dark matter in our solar system, even though there should be five times more mass from dark matter in our galaxy than ordinary matter (*MIT Technology Review*, 2013). The problem has grown since the LoP Interpretation was first published. A number of serious searches for dark matter have come up empty handed, as science journalist Eugene Bagashov (2017) explains.

Bruce Dorminey (2018), a writer who focuses on the latest research in astrophysics wrote recently:

> Decades after the first searches for dark matter’s hypothetical exotic particle counterparts, researchers are mostly at a loss to explain why there still has been no direct detection….
>
> Either some 85 percent of the universe’s matter is non-baryonic (or exotic) [dark matter particles], or there’s something awfully wrong with our current understanding of how gravity works on the largest scales.
>
> Although most researchers won’t state it publicly, more than two decades after writing my first article on the subject for the U.K.’s *Financial Times* newspaper, I sense an undercurrent of weariness with this vexing problem. (§ 1-3)

The reason why physicists proposed dark matter in the first place is because stars in the outer reaches of galaxies are moving too fast. These stars act as if there is five times as much matter in the galaxy than is visible. Unfortunately, this invisible dark matter is not distributed the way you would expect: It is spread out in the galaxy like a halo in such a way that the outer stars rotate as one body. Physicists cannot explain why matter would be distributed this way, but this is exactly what LoP theory predicts if the strong force is involved, because the strong force displays this exact pattern. The strong force acts linearly when inside the domain of its bond (Fritsch, 1983, p. 164).

This means that the force stays constant from near the center of its domain to the outer edges. Outside its domain, the strong force decreases at an exponential rate. The strong force is the only force that acts linearly, and this is exactly what we see happening with the outer stars in galaxies.

As a result, if dark matter is created by an all-for-one bond, then the stars should move as one, the same way that quarks spin as one inside of protons. See "proton spin crisis" in section 6.2.1 above.

This offers an explanation that is consistent with everything that physicists know about dark matter, and also, as far as I know, it offers a way to test the theory. We should not see any evidence of dark matter in our galaxy except for the added speed of stars, because we are looking at it from the inside. Also, the planets in our solar system should *not* move faster because planets are not inhabited by sentient agents. Only stars and galaxies are. Plus, we should only see the mass of dark matter in galaxies when looking at galaxies from the outside, such as with gravitational lensing effects (where light bends around galaxies – this is used to determine the location of dark matter).

However, if dark matter in galaxies is indeed caused by all-for-one relationships between the stars, then this means that those stars must also be bodies inhabited by sentient agents. Remember, all-for-one relationships can only exist between sentient agents. If this is true, then we must also see the evidence of dark matter in stars. If we cannot find evidence that this same behavior is at work in our sun, then the LoP theory of dark matter is wrong. This offers another test for the LoP theory of the strong force.

A recent study shows that there is evidence of dark matter in our sun. In fact, it explains a recently discovered problem that has stumped physicists: Why is the sun rounder than it should be? If atoms in the sun have joined together to form an all-for-one bond, because the sun possesses a sentient agent of its own, and this enables the sun to act as an individual unit, then we should see the atoms within the sun revolving together as one. This should make the sun noticeably rounder than gravity can account for. This is exactly what has been discovered (as reported in *Nature World News*, 2012). No theory of gravity or any other force is able to account for this added roundness.[14]

A number of recent discoveries have reinforced the reality of dark matter but have taken physicists by surprise because they are not things that a theory of "cold dark matter" particles would predict. All of these discoveries are consistent with the LoP theory, as far as I can see. To do this justice requires a dedicated study of its own.

Once again, we can see that the LoP Interpretation creates a number of surprising predictions that are testable. These all represent ways that LoP theory, or parts of the theory, can be challenged or even invalidated. The only reason I am presenting theories that sound so outrageous is because I have been looking for ways to prove them wrong over the last five years. They seem to hold up.

---

[14] See also Marman, 2016, pp. 258-270.

The case of dark matter is one of the most surprising examples, because confidence was strong, at first, that evidence of the missing dark matter particles would be found in tests at the Large Hadron Collider. Since then, test after test has reported a complete lack of dark matter particles, such as the recent experiment reported by Conover (2018).

However, that was just the beginning. Following are some more recent examples.

A galaxy has been recently found where little or no dark matter appears to exist. This is puzzling. Did the galaxy form in the first place with dark matter? If it did, then why did it suddenly lose all that dark matter? However, this makes sense according to LoP theory, because we should expect some galaxies to “die,” just like atoms decay and creatures have lifetimes (Drake, 2018).

Another study shows a surprising number of galaxies “rotating in sync” with each other. This makes sense, because if stars can form galaxies, then galaxies should also be able to form all-for-one relationships as well (Tasoff, 2018).

A recent study shows that there appears to be less dark matter in the earliest galaxies. Plus, those galaxies were much more turbulent, meaning that the stars were not spinning together as strongly, and they were filled with more gases and fewer stars. Is this not what we should expect for “young” galaxies, where all-for-one relationships are still developing stars? (Max Planck Institute, 2017).

And another new study says that dark matter is much darker than physicists thought. This means that dark matter does not appear to respond in any way to the EM energy in gases. This also makes sense because the strong force should only affect the stars, not clouds of gases because those gases are conglomerates, not individuals at the same level as stars (Nelson, 2018).

This also explains the Bullet Cluster, a famous formation created by two galaxy clusters that crashed through each other. The clouds of gases clearly attracted each other, but the dark matter centers did not follow the same path. They followed the centers of the stars in the galaxies instead, as the dark matter should if it is formed by an all-for-one relationship between the stars and the galaxy (Marman, 2016, pp. 265-266).

All of these recent discoveries are consistent with a strong force theory of dark matter. However, the most compelling evidence is just to see how spiral galaxies keep their form almost indefinitely. If gravity alone was involved, without any dark matter, the spiral arms should spin away. In other words, galaxies should spin apart, but they do not. They maintain their forms, the same as we see with the bodies of all individuals. The arms of spiral galaxies are not transient features, as astrophysicists once thought (Harvard-Smithsonian Center for Astrophysics, 2013).

This theory of dark matter is, of course, a speculation. A crazy one. It may even be crazy enough to be right, as Niels Bohr put it. However, it does at least show that there are new possible ways to interpret our natural world. And it shows that it is possible to meet Lee Smolin’s challenge: Any theory claiming to be a fundamental theory of nature must be able to explain all five problems.

6.4 Summary of Challenges and Opportunities

This shows what I believe are the biggest challenges that the LoP Interpretation faces. These issues represent areas where further research is clearly needed. Other opportunities can be found in my book, *Lenses of Perception* (Marman, 2016).

Presenting a theory that reaches across fields, such as quantum physics, biology, neuroscience, and psychology, creates problems of its own. However, the similarities across these fields suggests that we may have been missing something that a new interpretation of QM can help explain.

7. Conclusion

It is easy to assume that the lesson of quantum mechanics is that physics defines everything that happens in this world. After all, this is what classical physicists have been telling us for centuries. However, the LoP Interpretation arrives at a different conclusion: Physics is no closer to the foundation of reality than biology, psychology, or other social sciences.

In other words, biology and the social sciences can help us better understand quantum mechanics, just as much as quantum mechanics can now reveal important lessons for these other fields. Seeing the relationships between organisms and their habitat can give us a clearer idea of how particles live in this world. Seeing the way societies form among animals and insects gives us a deeper understanding of where quantum fields come from and what they are. Seeing the psychology of how we make decisions paints a richer picture of the wave collapse. The study of leadership not only gains new insights from the principles of quantum mechanics, it also gives us a more vivid sense of how the “strong force” works.

In other words, the LoP Interpretation shows us that there are huge benefits to be gained from cross-pollination between fields of study. Each uses a different lens and perspective. By comparing them, we gain added context and a deeper understanding.

The value of an interpretation should be judged by how useful it is in giving us new ways of looking at life and reality. Can it help make us more effective as leaders, as scientists, and even as people in search of meaningful lives? These are the real proving grounds for the LoP Interpretation.

If biology and social sciences gain something from a quantum understanding of relationships, then we have expanded the scope of science. It can now reach from the smallest particles to the study of human psychology, from the origin of life to the formation of organizations, from the forces that form atoms and molecules to the chemistry of societies and how they interact. This breathes a new sense of life and open-endedness into scientific disciplines that have normally been limited to the closed-system, mechanistic perspectives that come from third-person lenses.

This also suggests that there may be a common thread tying all fields of science together because everything that happens is governed by relationships between living agents. If nothing else, hopefully, this paper opens the door a bit to new ways of looking at our natural world.

Acknowledgments

Special thanks to the following for their helpful suggestions and comments, which helped lift this paper into something much better than how it began: Ruth Kastner, Alan Rayner, Markus Molz, Bonnitta Roy, Jonathan Reams, and Karla McMechan.

Vertical Transformation of Leadership Culture

John B. McGuire[1] & Charles J. Palus[2]

Abstract: This article defines leadership culture and provides a framework for its vertical (aka constructive-developmental, or transclusive) transformation. The idea of leadership culture and its developmental potential has been a key focus of research and practice at the Center for Creative Leadership since the mid-1990s, as CCL began transcending and including its domain of developing individual leaders within an explicitly relational ontology. The Direction, Alignment, and Commitment (DAC) Framework models leadership as a relational process operating at both individual and collective levels, in which beliefs and practices for creating DAC are shown to develop vertically. Collaboration with Bill Torbert and associates has produced a model of leadership culture transformation in parallel with the action logics observed in individual leaders. The second part of this article describes an approach to change leadership via multi-year collaborative inquiries grounded in culture. The Change Learning Cycle integrates three intertwining domains of change: self, cultural beliefs, and systems. Finally, the article outlines the use of a leadership culture toolbox for change leadership initiatives designed for engaging, scaling, and democratizing leadership culture development for everybody, everywhere.

Keywords: Change leadership, interdependent, leadership culture, toolbox, Torbert, transclusive, vertical development.

Introduction

A distinctive feature of our time is that cultures of all kinds are proliferating, splitting, combining, and evolving. The destructive polarizations apparent in society are largely culturally driven. “Culture” used to be a comforting word that implied stability and civic cohesion. Culture has instead become a frightening word amidst the churn of global identity politics. What is the

---

[1] **John B. McGuire** is a Senior Fellow at the Center for Creative Leadership, specializing in Leadership Culture and Change Leadership. He is an international authority on leadership culture and organizational transformation, and co-founder of the Organizational Leadership practice, having served as Transformation Practice Leader. As a researcher-practitioner, John’s innovation essentially reforms traditional change methods to be consciously driven through the senior leadership’s culture, beliefs and practices. He has researched and published widely including the book Transforming Your Leadership Culture. John has assisted organizations across multiple sectors, and previously held senior business management positions across industries. He holds master’s degrees from Harvard and Brandeis Universities.

solution? We must evolve in ways never before imagined. New and better leadership is required but our 20th century models and techniques of leadership development are insufficient to the challenges. A new paradigm is emerging in which the development of individual leaders is included and transcended by taking *leadership culture* itself as a primary unit of human development. Leadership cultures produce leaders. Polarized cultures produce polarized leaders--usually. A leadership culture is itself a kind of living entity, with evolving memetic beliefs, practices, and artifacts. We propose a class of memetic social entities or systems called *leadership culture*, members of which change, develop, and intertwine in ways we are learning to observe, describe, and influence. Leadership cultures are where we live, and for our collective well-being we need them to be healthy and thriving (Palus, Harrison, & Prasad, 2015).

The way forward, we think, lies in making leadership culture visible, understandable, and intentional. This means making leadership culture itself the object of the kinds of intensive development efforts that in the past have been focused on individual leaders. We know now that leadership cultures can evolve, and can be intentionally shaped, to higher levels of collective awareness, efficacy, and moral action. We live in a time of accelerating cultural dynamics, of remarkable growth as well as damage and decay. The vertical development of leadership cultures amidst this churn is possible, promising, and necessary.

In this article we describe a body of theory and practice for change leadership, with leadership culture as the main arena for intentional, strategic change in organizations and communities. The vertical development of leadership culture, in concert with individual, team, and societal development, enables the execution of complex strategies in increasingly challenging contexts.

Our maxim is:
If you want best practices, you need best beliefs.
Beliefs drive practices.
Beliefs are embedded in cultures.
Culture always wins.

The key question becomes:
How can you evolve and transform your culture around best beliefs?

Our Work

The co-authors of this article are Senior Fellows of the Center for Creative Leadership (CCL) who work with clients in a wide variety of leadership development contexts at the levels of individual leaders, group effectiveness, organizational leadership, and societal advancement.

Our mission at CCL (www.ccl.org), a 50-year old non-profit research-based organization, is to advance the understanding, practice and development of leadership for the benefit of society worldwide. Our vision is to positively transform the way leaders, their organizations, and our societies confront the difficult challenges of the 21st century.

The idea of leadership culture and its vertical transformation has been a key scaffold of research and practice at CCL since the mid-1990s, as CCL began transcending and including the psychological paradigm of individual leader development within a more encompassing sociological and relational ontology (Drath & Palus, 1994; Palus & Drath, 1995; Drath, 2001; Drath et al., 2008).

The Center for Creative Leadership and Bill Torbert's Global Leadership Associates (www.gla.global) are partner research-practitioners focused on the development of leaders and leadership cultures. Over the years we have theorized and explored leadership action logics at the collective, organizational level, and we have collaborated in change leadership initiatives. Our research methods are modeled on Torbert's rich framework of Collaborative Developmental Action Inquiry as we work with clients and partners in human development – and as we seek to transform ourselves and our own cultures and societies (McGuire, Palus & Torbert, 2007).

Over the long-term, at its best, this shared inquiry has been a dance of possibilities, insights, and mutual transformations among people who are passionate about human development. In this article we synthesize what we and our collaborators have learned about the vertical development of leadership cultures across several decades, around the globe with a practical bent toward more effective organizations and a healthier world.

Part 1: Leadership Culture Theoretical Frameworks

This body of work begins with the application of relational and pragmatic theory and philosophy (Gergen, 1994; Dewey, 1958) to leadership. Leadership is thus understood in terms of participating in, shaping, and constructing shared beliefs, practices, systems, and artifacts in service of certain kinds of shared outcomes. Leadership is meaning-making in service of collective action. We align with those seeking leadership in plural, collective, and complex systemic terms (Denis, Langley & Sergi, 2012; Ospina & Uhl-Bien, 2012; Drath et al., 2008; Uhl-Bien, 2006; Drath, 2001). We describe the relational point of view in terms of the DAC ontology for leadership development at the multiple levels of individuals, groups, organizations, and societies (SOGI) more broadly.

Upon this pragmatic, relational foundation we build our change theory and practice with the findings of individual constructive development (McCauley et al., 2006), learning theory and practice (McCarthy, 1996; Argyris, 1990; Senge, 1990), integral theory and practice (Wilber, 2000; Torbert, 2004); cultural anthropology and ethnography (Bohannon, 1995; Schensual & Lecompte, 2016), and organizational leadership strategy (McGuire & Rhodes, 2009; Denison, 1997).

We draw on all of this to describe and engage leadership cultures. Leadership cultures are the bodies of shared beliefs and practices in a collective that shape what "leadership" means (implicitly and explicitly) and thus determine how leadership is recognized, practiced, and developed. Because:

Culture always wins.
And:
Cultures evolve and transform.

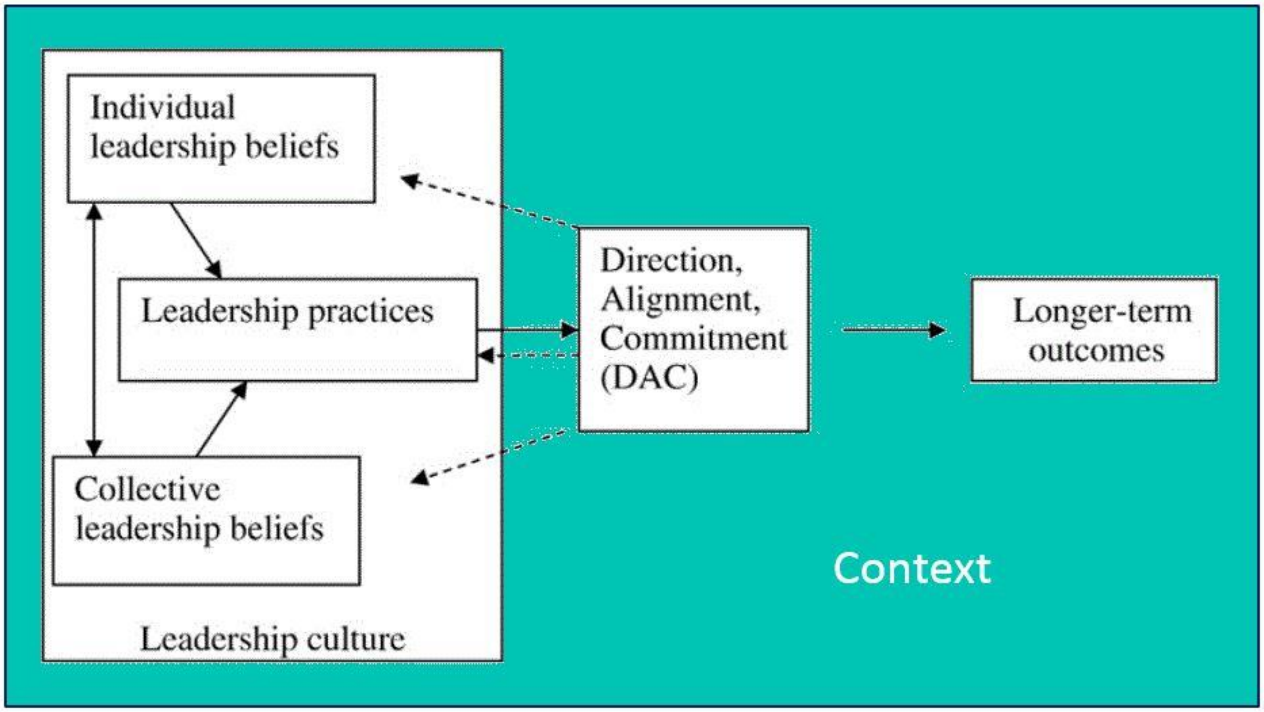
Leadership cultures can evolve vertically, such that later action logics come to *transclude* (transcend and include) earlier ones. The potential rewards are greater maturity, agility, wisdom and collective ownership of the whole enterprise; and efficacy in volatile, complex, and uncertain times (Torbert, 1987). The vertical development of leadership culture is thus crucial to creating and sustaining organizational growth and change in the face of complex challenges.

Let's take a look at what we know and what we are still learning about the vertical transformation of leadership cultures.

The Relational Ontology and Leadership Culture Transformations

What one believes about the underlying nature of leaders and leadership drive one's organizational practices and strategies.

The Center for Creative Leadership has adopted the DAC Framework (Drath et al., 2008) across all our practice areas including Organizational Leadership. The DAC Framework is the basis for the theory and practice described in this article (Figure 1). *Direction* is agreement on shared goals. *Alignment* is the organization of work. *Commitment* is the willingness to subsume individual interests for the good of the collective. Note that the terms "leaders" and "followers" per se do not appear in the primary model, as they are derivatives of relational beliefs and practices for producing DAC.



Individual leadership beliefs
Leadership practices
Collective leadership beliefs
Leadership culture
Direction, Alignment, Commitment (DAC)
Longer-term outcomes
Context

Adapted from Drath et al., 2008

Figure 1: The Direction, Alignment, and Commitment (DAC) Framework

In the relational ontology*: Leadership* is a social process, embedded in cultural beliefs and practices, which shapes and creates the collective outcomes of direction, alignment, and commitment (DAC). Leadership *development* is the growth and transformation of these DAC-shaping capabilities within a collective, at the multiple levels of individuals, groups, organizations, and societies. These multiple levels of leadership development and outcomes and their nested structure (Yammarino & Dansereau, 2008) are represented by the useful acronym SOGI (Palus, McGuire & Ernst, 2011).

Until recently, almost all theories of leadership derived from psychological ontologies in which leadership is situated within the character and personal competencies of individual leaders. Psychological ontologies take individuals as primary with relationships as by-products. A systemic version of this is that individuals reciprocally shape one another, like the Escher of hands drawing one other. Ontologically however, and in the long run, it is relationships all the way down. “Human being” is fundamentally a plural and social verb.

Earlier in our work, we experienced the benefits and then the limits of a primarily psychological approach to leadership development. Often the development of the individual was obvious and measurable, while the impact of this development on organizational or societal outcomes was not as apparent. These limits gradually became a crisis in the 1990s as disruption increased in the forms of re-engineering, downsizing, de-regulation, and globalization. One leader at a time was not enough anymore.

We began experimenting at the edges of our limits, and proposed a new, relational starting point for leadership development: What if we shifted our understanding to imagine “leadership as meaning-making in a community of practice” (Drath & Palus, 1994). It was an invitation to inquiry as much as a definition. This reframing of leadership proved to be controversial—and a useful powerful shift for many in our network of colleagues and clients (Ospina & Uhl-Bien, 2012).

A relational ontology focuses on capabilities shared *between* leaders, including but going beyond the characteristics found *within* individual leaders. This shift from “within” to “between” as the primary focus of leadership development raises important questions: What constitutes a community? And: How is meaning made?

Two lines of response are especially fruitful.

The first response is constructive-developmental (aka vertical or transclusive). In this view, the key defining feature of humans is the construction of meaning (Kegan, 1994). We live our lives in various webs of belief (Weick, 1979; Quine & Ullian, 1978; Kelly, 1955). Practices are beliefs and meanings put into action (McGuire & Palus, 2015).

Constructive-developmental theory posits human development as a succession of increasingly complex and mature stages and states of meaning-making that frame thought and action (McCauley et al., 2006; Piaget, 1954). Leadership development is closely related to this kind of increasing maturity (Palus & Drath, 1995). More mature leadership is capable of attention to timely action, further horizons, and more complex challenges (McGuire & Rhodes, 2009).

This is often referred to as *vertical* development (Cook-Greuter, 2013), such that the metaphorical direction of development is vertical or "up," the proverbial direction of aspiration and achievement. But, the vertical metaphor can also be distracting and limiting, implying a strictly linear, ladder-like, and "better-than" progression. A more nuanced perspective posits a *multarity* or multiple polarity of dynamically interacting stages, states, and relationships (Johnson, 1992). Development in real life is messy and enigmatic (Herdman-Barker & Wallis, 2016).

The useful synonym *transclusive* development highlights the key polarity of each stage as *both* transcending *and* including earlier ones, and anticipating later ones (because we are prepared by culture), producing bigger, more agile, complex, and connected minds—as compared to merely elevated or chronologically-older ones.

We define *transclusion* as a primary pattern of growth, evolution, and development in which a new, more complex perspective or logic emerges in a system which transcends and transforms existing perspectives, while at the same time including, assimilating, and re-integrating established logics and perspectives into a new dynamic structure.[3] Development as transclusion is web-like and nested rather than linear. Such attention to the central role of language in this work reminds us that consciousness itself is social, metaphor-based, memetic, and evolving (Hofstadter & Sander, 2013; Jaynes, 1976).

The second response is cultural. Anthropologists define culture as the tools and meaning (beliefs) that extend learning, expand behavior and channel choice (Bohannon, 1995). All meaning-making is embedded in cultures ranging from societal-scale to the local cultures of groups, teams, and organizations (Cameron & Quinn, 1999). Cultures are holding environments for individual and collective meaning-making (Kegan, 1994; Schein, 2010). The labels we tend to put on individual leaders have cultural roots and relational branches. Yet cultures can seem invisible from the inside. We are like fish in water. We are in it, and we can't see it (Wallace, 2005).

Cultures can evolve and transform vertically, that is, toward greater complexity and interdependence in the dynamics of leadership. The dynamics of power, authority, participation, collaboration, and perspective-taking, and self-development benefit from intentional development (Kegan & Lahey, 2016; McGuire & Palus, 2015). This has been observed in regional cultures (Inglehart, 1997) as well as organizational cultures, and in leadership cultures (McCauley et.al. 2008). Bill Torbert in particular has advanced the idea that team and organizational cultures can develop in predictable stages which parallel and echo the stages of adult development (Torbert, 1987).

Leadership culture is the self-reinforcing, evolving, memetic web of individual and collective beliefs and practices in a collective for producing the outcomes of shared direction, alignment, and commitment. The complexity of an organization's strategic work is linked to the capability of its leadership cultures – typically plural in nature--to handle that complexity. This includes the collaborative capability to span boundaries among the multiple sub-cultures present in most organizations and communities (Ernst & Chrobot-Mason, 2010).

---

[3] The term *transclusion* is transposed and adapted from the Xanadu hypertext epistemology of Ted Nelson (1993), which also suggests that human meaning-making and its development is *intertwingular* and non-linear. We are grateful to Al Selvin and Simon Buckingham Shum for exploring the use of hypermedia-supported dialogue mapping in the context of leadership development (Selvin & Buckingham Shum, 2014).

Strategy requires the right culture, one capable of its execution (Hughes, Beatty, & Dinwoodie, 2013). Culture always wins. Keen strategy, changes in behavior, new competencies, and best practices are necessary but not sufficient for leading in times of turbulence and change. Culture development – evolution and even transformation -- is required for effective leadership in support of bold strategic aims.

Leadership culture is the operating system for producing DAC in a collective. But not every operating system is capable of enacting a complex and agile strategy.

With these insights in mind, we began to explore, model, and test the following idea in collaborative inquiry with our clients and colleagues:[4]

How might leadership cultures develop in ways that support learning, growth, and change in the face of complex challenges?

To do this, we needed a practical framework and tools that would help make leadership culture more visible and provide some shared language and images, allowing members to observe, reflect and converse about their past, present, and desired leadership cultures. Thus we needed a simple, face-valid, and roughly accurate model of leadership culture development. In these practical terms a 3-stage model is more accessible, memorable, and useful than a 5- or 7-stage model.

We landed on the model shown in Figure 2 (the "Snowman" model) in which organizational cultures can be understood as variations, combinations and progressions of *dependent*, *independent*, and *interdependent* leadership logics (Palus & Drath, 1995; McGuire, Palus, Torbert 2007, McCauley et al., 2008; Laloux, 2014). Each successive leadership logic transcends and yet includes, accommodates, and incorporates the earlier logics, so that a culture of interdependence is ideally capable of integrating dependent and independent logics into a kind of collective maturity. Each is more capable than the one before of accepting and managing the tensions and paradoxes present in complexity.

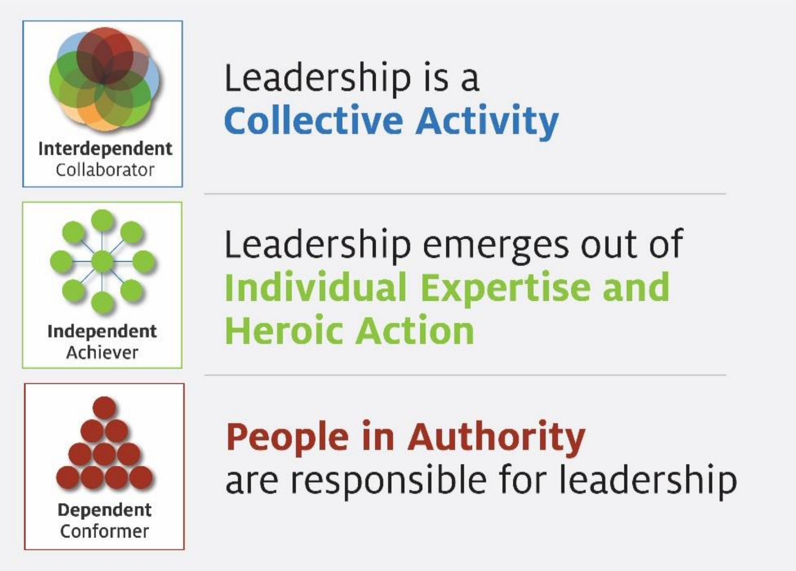


Figure 2: Three states and stages of leadership culture (The Snowman)

---

[4] Details are reported in Palus, McGuire & Ernst, 2012; McCauley et al., 2008; McGuire & Rhodes, 2009; McGuire & Palus, 2015; Hughes et al., 2011; Drath, Palus, & McGuire, 2010; McGuire, Palus, & Torbert, 2007; Palus & Drath, 1995; Palus & Horth, 2002.

These three categories are based in the classic summation of the maturing human mind as a sequence of three phases, variously framed as *traditional, modern & post-modern* orders of consciousness and reasoning (Wilber, 2000; Kegan, 1994; Inglehart, 1997; Kohlberg, 1969; Covey, 1989); phases of values as *survival*, *belonging*, *self-initiation* & *interdependence* (Hall, 1995);); *conformer*, *achiever* & *collaborator* leadership logics (McGuire & Rhodes, 2009); and *dependent, independent & inter-independent* cultural logics (McCauley et al., 2006; Palus & Drath, 1995).

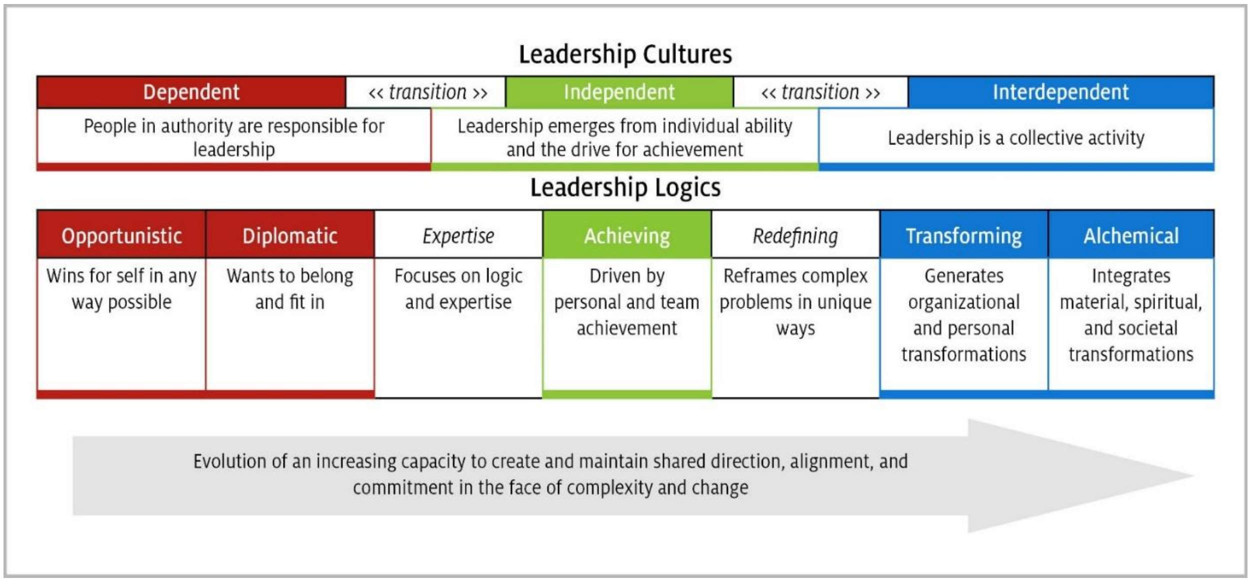
Cultural beliefs and practices determine how DAC outcomes are realized (Figure 3). *Dependent* leadership cultures cultivate DAC by authority and tradition. *Independent* cultures cultivate DAC by a cadre of achievement-driven leaders utilizing technical expertise primarily for their own purposes. *Interdependent* cultures cultivate DAC using intentional sense-making processes across otherwise independent entities and are strategically engaged in external societal networks (Drath, Palus, & McGuire, 2010).

	Direction How do we achieve agreement on direction?	**Alignment** How do we coordinate our work so that all fits together?	**Commitment** How do we maintain commitment to the collective?
Interdependent	Agreement on direction is the result of **shared exploration** and the **emergence** of new perspectives.	Alignment results from **ongoing mutual adjustment** among **system-responsible** people.	Commitment results from **engagement in a developing community.**
Independent	Agreement on direction is the result of **discussion, mutual influence,** and **compromise.**	Alignment results from **negotiation** among **self-responsible** people.	Commitment results from **evaluation of the benefits for self** while benefiting the larger community.
Dependent	Agreement on direction is the result of willing **compliance** with an **authority.**	Alignment results from **fitting into** the expectations of the **larger system.**	Commitment results from **loyalty** to the source of authority or to the community itself.

Figure 3: DAC and leadership culture

To be clear, all these forms of leadership are relationally produced, and all have utility in specific settings. For example, heroic individual leaders are authorized and empowered by cultural norms (Yammarino, et al., 2012). Thus leadership development *always* benefits from a relational understanding even when strong individual leaders are the object of development: Culture always wins.

Recently, interest in vertical leadership development has expanded and our clients are requesting more insight into the underlying constructive-developmental models (Petrie, 2014a, 2014b). Our 3-part Leadership Culture Model is useful for clients gaining awareness, prompting dialogue and groups learning in action; and is less precise for fine-grained assessment and formal evaluation.



Leadership Cultures
Dependent
<< transition >>
Independent
<< transition >>
Interdependent
People in authority are responsible for leadership
Leadership emerges from individual ability and the drive for achievement
Leadership is a collective activity
Leadership Logics
Opportunistic
Diplomatic
Expertise
Achieving
Redefining
Transforming
Alchemical
Wins for self in any way possible
Wants to belong and fit in
Focuses on logic and expertise
Driven by personal and team achievement
Reframes complex problems in unique ways
Generates organizational and personal transformations
Integrates material, spiritual, and societal transformations
Evolution of an increasing capacity to create and maintain shared direction, alignment, and commitment in the face of complexity and change

Figure 4: Action logics of leaders and leadership cultures

Inspired by Bill Torbert's adaptation of individual action logics as cultural memes, we correlate the three cultures across the seven action logics (Figure 4) (McGuire, Palus, & Torbert, 2007; Rooke & Torbert, 2005). The names of these seven logics are shifted so that each word-ending better indicates a relational process rather than a personal label: *Opportunistic, Diplomatic, Expertise, Achieving, Redefining, Transforming,* and *Alchemical*. These logics are shared understandings and relational channels for beliefs and actions. The focus shifts and expands from labels of individuals in particular stages to the shared logics active in cultures and societies. *Expertise* and *Redefining* thus represent the key cultural transformations—to independence, then interdependence—within collectives. These seven *leadership logics*, now re-imagined as relational, provide a more refined and precise description of development, with transitional states, across the three broader leadership cultures.

The action logics of *diplomatic*, *expertise*, and *achieving* are by far the most common measured in organizations (Torbert, 2004). Conversely, the relative lack of more mature *redefining*, *transforming*, and *alchemical* action logics limits the prospects for sustainable and effective organizational change. All the while, in many of our contemporary settings, we seem to be increasingly up to our necks in narcissists and *opportunists*.

Challenges in Changing Leadership Cultures toward Interdependence

We share this axiom with client executive teams, in light of the stark realities of the global situation:

> *There is a hierarchy of cultures, and each successive leadership culture is capable of dealing with more complexity, more ambiguity and more uncertainty.*

We live inside the challenges of an interdependent world in the state of churn and evolution often called VUCA: volatility, uncertainty, complexity, and ambiguity (Stiehm, 2002). Our clients and their partnership networks are drawn to the possibilities of interdependent leadership cultures as an antidote to the churn and instability of global change (McGuire, Tang, 2011). Leadership requirements for executing complex strategies are alternately expressed as cultures of collaboration, resilience and agility; organizational learning, creativity and innovation; strategic leadership, and even forms of social responsibility. These qualities are relational, and can be realized most effectively within and among interdependent leadership cultures and their constituent beliefs and practices. The primarily horizontal cross-boundary nature of supply chains and the complexity of the relational networks of organizational partnerships required to operate within them, necessitates effective business strategies that increasingly embrace VUCA (Johansen, 2012).

In our experience, senior leaders have increasingly come to recognize the limits of independent-achiever leadership give way to the need for more interdependent-collaborative forms of leadership, and usually seek more mutual work in strategically critical locations and processes. And, dependent-conformer cultures also often seek change into more independent-achiever forms while often struggling to broaden toward change perspectives sufficient for scaling contexts. Some organizations have redefining aspects to their leadership culture which are adaptive and even generative toward more interdependence (W.L. Gore, Google, US Army) while organizations with strong expert cultures did not adapt (Digital Equipment Corporation, Lehman Brothers; DuPont).

Interdependent leadership beliefs and practices, we propose, can be understood as the *both/and* capabilities of double-loop and triple-loop learning (Argyris 1990; Torbert, 2004), the management of polarities (Johnson 1992), through dialectics and dialogue (Basseches, 1984; Bohm, 1990; Isaacs, 1999), and the capabilities for inter-systemic thinking and acting in the face of complexity (Oshry, 2007). Earlier leadership cultures are restricted by *either/or* mind sets and bridled by the limits inherent to compromise.

Intentional transformation to a leadership culture of interdependence is feasible under the right circumstances. The United States began as a *dependent* culture—a group of colonies under the authoritarian rule of the king. Rebelling against this oppression, colonists developed more *independent* minds. The U.S. Constitution expresses a form of *interdependence* that uses authority and compromise as tools within a broader vision of collaboration, new frontiers, and invites further transformation (Palus, McGuire & Ernst, 2011). But the question remains, does the citizenry have critical mass for a both/and mind-set required by the management of tensions embedded in the constitution (McGuire, 2010)?

PART 2: Change Leadership Core Realities

At the Center for Creative Leadership we practice action science with client partners, experiencing both the failures and successes of transformation in leadership cultures and organizations. This quote represents contemporary client realities.

> *In a fundamentally interconnected world our leaders face new and greater challenges that require new and greater leadership strategies. … Our future performance will increasingly*

> *require our top leaders to think and act interdependently – and above all to influence the men and women throughout our company to think and act interdependently – to move toward a higher organizational aim.*
>
> (Bob McDonald, Chairman and CEO, Proctor & Gamble, 2012) [5]

The world is shifting in such magnitude that it outstrips our experience and traditions. The extreme pace of change and the need to adapt is a daunting reality. We are slow to adapt and we simply react. We need more effective leadership in these times of change (Johansen, 2012).

Linear "eight stages of change management" processes may work within discrete operations projects, and with technical problems that can be solved. Attempting to lead change through conformance to standard operating procedures, or through the independent verve of experts and achievers can succeed through will power, but eventually hits the wall when executing a complex strategy full of real interdependencies (Oshry, 2007; Gryskiewicz, 1999; Beer, 1985).

The real space of change – and thus its challenge – is beyond the boundary of the change plan, the experts and the Gantt charts. That's where the change dilemmas emerge, full of paradox and complexity, in simultaneous and constant layers, waves and assaults.

For three decades the challenges that must be faced have not been being effectively managed or led, and the significant failure rate of change management in large organizations persists (Reeves et al.; Pasmore, 2011; Cameron & Quinn 1999; Kotter, 1996). The nature of organizational change itself is changing from earlier forms of project or initiative driven change and now towards more continuous forms of change that are more difficult to measure (Roth, 2011; Pasmore, 2015).

Senior leaders want – need – to live in a *strategic zone*, a place where mindset, knowledge and action are fused to continuously improve performance. In this zone, leaders are better able to manage risks, find opportunities, and establish and leverage competitive advantages. They create an operational edge and play it to improve the probability of success.

Leaders working interdependently in the strategic zone are connected and agile, informed and open, attuned and aware. They are able to respond deftly to change and guide others to adapt as well.

While change management is the technical, empirical mechanism (*outside-in*) aspect of transformation, change leadership holds the mindset (*inside-out*) of beliefs, imagination, emotions and human spirit. Change management and change leadership are the two sides of a Mobius strip.

The strategic zone is collaborative. Like teams of mountain climbers attuned in interconnecting relationships, leadership itself is increasingly understood as a shared space (Uhl-Bien, 2006. Drath et.al 2008. Denis, Langley, Sergi 2012). Leadership mindsets are shifting toward more interdependent and collective leadership capabilities (Palus, McGuire & Ernst, 2011).

---

[5] Hughes, Beatty, Dinwoodie, 2013

Individuals, working in teams, must still develop greater skills and competencies but that is not sufficient. A shift in the leadership culture is typically needed to bring executives, senior teams and key leaders across an organization into the strategic zone (McGuire & Rhodes, 2009). A comprehensive leadership strategy in tandem with a business / organizational / societal strategy is required (Hughes, et al., 2011; Pasmore, 2009).

The big challenges of leading interdependently in the strategic zone require bigger minds. Achieving and growing bigger minds – both individually and collectively – is vertical development territory. Vertical development is categorically different than horizontal development (Petrie, 2014a).

Horizontal development means instilling more skills and competencies into leaders. It is most often about technical knowledge which can be collected, measured and displayed. It is about *what* you think and believe.

Vertical development is the advancement of capacities for awareness and imagination, and becoming able to feel, conceive, believe and think in more complex, curious, systemic, strategic and interdependent ways. It is about *how* you think and believe.

With these basics in mind, let’s look at how change leadership in the strategic zone actually works.

The Realities of Change Leadership

> *It is important to keep in mind that the objectivity of the institutional world, however massive it may appear to the individual, is a humanly produced, constructed objectivity.*
>
> (Berger and Luckmann, 1966, p 78)

Reality, in other words, is socially constructed (Berger & Luckmann, 1966). This somewhat obvious statement is controversial when it is taken as an either / or choice. Of course organizational reality is *both* socially constructed *and* physically constructed (Ospina & Sorenson, 2006). Vertical development as a mature adult includes being better able to grasp such apparent contradictions and polarities in their full both/and complexities (Johnson, 1992). This realization allows us all to be “social constructivists” and also embrace nuanced objectivity (Kegan, 1994).

Social construction is what change leaders do together. Change leadership is largely (but not only) a matter of imagination, curiosity, communication, dialogue and meaning-making. Meaning-making is to leaders as brick-laying is to builders.

For mature leadership in terms of vertical development, the preferred path of social construction is variously referred to as collaborative-developmental action inquiry, or CDAI (Torbert, 2004), participatory inquiry (Reason, 1994), collective mindfulness (Weick & Sutcliffe, 2006), and the learning organization (Senge, 1990). We often refer to such intentional, reflective, curious, truth-seeking, imaginative, playful, collaborative, action-oriented forms of social construction simply as *public learning* (McGuire & Rhodes, 2010).

Public learning, in this view, holds, nurtures, and (ideally) synthesizes and advances three perspectives which are fundamental to constructing the human realities of organizations of all kinds (McGuire, Palus, & Torbert, 2007). *First-person perspective* is personal and based in individual experience, reason, feeling, intuition, faith, etc. *Second-person perspective* is mutually constructed in relationships as "our" view. *Third-person perspective* is about objective, verifiable, material facts.

These three perspectives come together in the conversations and dialogue we have with each other. Public learning is the experience of intentional dialogue applied in real-time to strategic organizational or societal work. Public learning is both serious and playful, entertaining both/ands and reconciling multiple truths. Emotional intelligence is requisite.

Reality is worth constructing together. Collective wisdom is worth creating. Truth matters. Truth is worth pursuing. We mean *the pursuit of truth* as the curiosity and intent to be conscious in relationship with each other, advancing our knowledge through a shared process of discovering, understanding, and transforming our reality.

From our own public learning in our journeys among change leaders, we offer *Three Realities of Change Leadership*. We hold these social constructions as open for dialogue in the global community of people who lead, manage and deal with change: All of us.

First Reality

Successful change requires both change leadership and change management.

Leading change requires understanding the differences in leading and managing.

Change management enacts the technical operational systems, structures and processes required to enact the business strategy.

Change leadership develops the capabilities for realizing shared direction, alignment, and commitment required to enact the business strategy.

Change leadership is the process of setting a leadership strategy to identify the leadership and culture dimensions of what it takes to deliver promised results (Beatty & Byington, 2010).

Change leadership is the craft of agile leaders capable of seeing whole systems while operating and integrating them. It is public learning in action.

Change leadership is needed to continuously elicit the direction, alignment and commitment to thrive in a complex and changing world.

Second Reality

Attention to leadership culture is key to strategic success.

Leadership culture will make or break any strategy, change effort or business transformation.

Complex, multifaceted, systems-level shifts in the environment require mindsets big enough to deal with continuous waves of change. Curious, intentional, both/and thinking, creative, interdependent leadership is what's missing.

Most leaders underestimate the risk of getting culture wrong. Instead, they focus habitually on the measurable, controllable, technical expert side – they manage the business. While technical tools, systems and processes are necessary instruments, they are nothing without culture. The evolving, bigger mind is both individual and cultural in nature.

Different types of leadership culture are likely necessary across different parts of any organization, but to succeed in the long run, most organizations need to build toward cultures of greater interdependence. Interdependent leadership cultures of collaborative, connected and shared leadership are needed for systemic perspective-taking required to respond to complex and changing environments.

Third Reality

Public learning is the means to a more interdependent leadership culture.

Sustainable change is a permanent learning process embedded in an organization's work (Quinn & Van Velsor, 2010). It is quite different than technical change. Public learning is required. In most leadership cultures, engaging in open, public, learning conversations is not a natural act. Bigger minds are required to lead public learning.

Many cultures impede public / collective / collaborative learning. Conversations necessary for learning and change are avoided or condemned (Patterson et al., 2002). Social norms prevail over organizational effectiveness. As tragic as organizational change failure is, saving face is often more important than saving the organization.

Culture always wins.

Change leadership requires having open dialogue to reveal beliefs that drive decisions. It is about mining key nuggets of knowledge in action, and hammering them into useable information that can be applied and modified into the actual work of changing systems and processes. Learning is confirmed in the collective conscious process, and happens individually and collectively, simultaneously and through the organization's work.

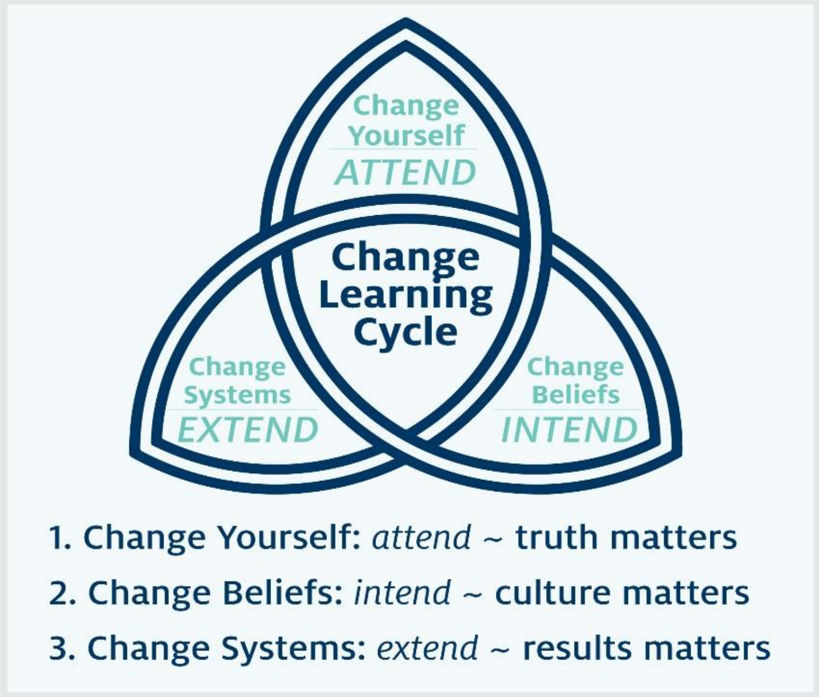
Collaborative leadership cultures are new on the horizon. They are increasingly capable of engaging in deep dialogue, uncovering hidden assumptions, and generating multiple right answers. It takes both/and thinking, facility with paradox, and interdependent mindsets to master this unfolding arena of complex change.

Senior leaders in the strategic zone understand the nature of interdependence and require increasingly interdependent forms of leadership within key strategic organizational zones in order to execute increasingly complex strategies. They recognize the need for collaborative networks of leadership throughout the supply chain, linking silos, sharing knowledge and learning strategically together (Palus, Cullen, Chrobot-Mason 2016, Pasmore, 2015). They understand the necessity of shared beliefs and practices for a co-created future.

Part 3: Leadership Culture Change Learning Process & Tools

Change learning is at the heart of change leadership (Argyris & Schön, 1996; Schein, 2010; McGuire & Rhodes 2010). Through both private individual and collective public learning, leaders advance new beliefs, practices and repeated behaviors that create alignment across the organization's systems, structures and processes. They learn how to make different, better decisions. Teams learn how to argue constructively, think systemically, change beliefs, make better decisions, and create new waves of practices.

We've constructed for practical purposes a three-part cycle. This is a change learning process that expresses the basic dynamics of individual and organizational learning in the change and transformation process (Figure 5),



Change Yourself
ATTEND
Change Learning Cycle
Change Systems
EXTEND
Change Beliefs
INTEND
1. Change Yourself: attend ~ truth matters
2. Change Beliefs: intend ~ culture matters
3. Change Systems: extend ~ results matters

Figure 5: The change learning cycle

ATTEND Change *yourself*. Attend to what's going on inside yourself and others. Pay attention.

Change at an organizational level requires change within individuals. Culture is fostered by leaders attending to change in themselves, as they try out ways of working differently, and different ways of constructing reality with others.

Senior leaders must do the change work first. They serve as role models and guides. They shape the norms of culture, every day, by how they communicate, decide, focus and relate to others. They create environments in which *who we are*, *what we believe* and *how we do things around here* determine how we set and achieve our goals, develop our capabilities and insure our long-term viability.

The idea for many senior managers to change themselves first, rather than delegate change to others, is often quite challenging and counter-intuitive. Further, the notion to dig down and change beliefs as the key lever for changing behavior is often novel for many executives.

Changing one's self requires reflective capability. If you don't have the capability to be self-aware/conscious, to be consciously observant about what's going on around you and what's going on inside you at the same time, then your ability to participate in change may be meager.

Change leadership demands that leaders pay attention. It demands that we discover and construct reality, individually and collectively. It is about being curious about what is really happening, and what is true in a situation so that we can figure out what else could be true.

If you want *change*, *consensus reality matters*. You have to be serious about the *pursuit of truth.*

INTEND Change *beliefs*. Test and revise shared truths. Serve your purpose.

Intention is the linkage between the desired, identified change and how change becomes reality.
The shift to intention takes place one conversation at a time. It is about slowing down to power up, becoming conscious in the moment as work gets done and decisions get made. Through both structured and unstructured conversations and work, senior leaders begin to "test drive" new beliefs. As beliefs shift, decisions and behaviors will also shift, resulting in different actions and new outcomes.

Old assumptions have to shift toward new beliefs for organizations to evolve. This requires leaders to deliberately question assumptions alongside their peers, who are also intending to develop the beliefs and practices needed to achieve the strategy.

Beliefs drive decisions, and repeated decisions are practices. By design and with intention, the leadership culture and the operations change simultaneously. Performance – the motivation for change – begins to change, too.

If you want best practices, you need best beliefs.
If you want best beliefs, then intentionally evolve the leadership culture.

EXTEND Change *systems*. Extend the new beliefs and mental models into revised systems and processes aimed at strategic results.

As senior leaders learn together – through *attention* and *intention* – they *extend* that knowledge into organizational systems and processes, achieving change targets and making the goals.

Culture change is done for an organizational purpose. What is required to implement the strategy? What is needed on the human, social and cultural front – alongside the technical and structural needs – to implement change, respond to complexity and realize the future required?

Increasingly, organizational strategies require interdependent mindsets for execution. But organizational members are not yet operating with the intentions and beliefs required to work collaboratively. The whole proposition shifts when senior leaders extend the attention and intention of public learning into more and more places and with more and more people. It becomes the new way of working.

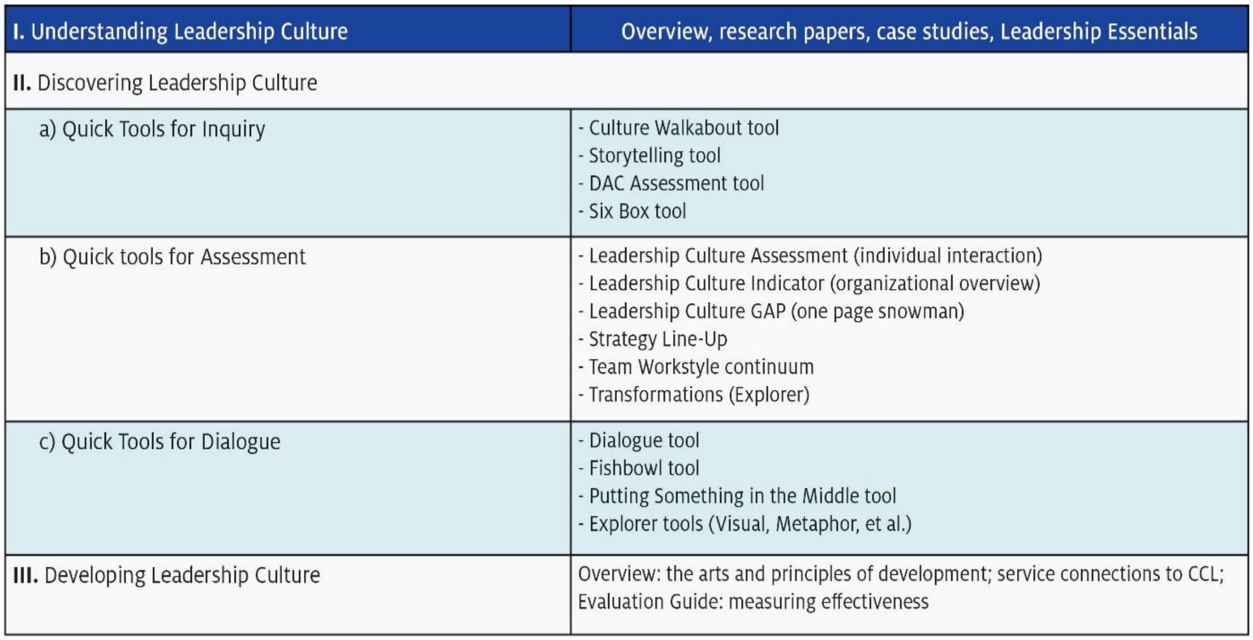
If you want *reliable results*, you need *sustainable*, *interdependent human systems*.

Leadership Culture Quick Tools for Action Development

Practical tools are required to make the learning work of change leadership accessible and useful to managers and leaders. The content alone is not enough. Ease of use is essential.

We have reduced the use of "outside-in," quantitative surveys and increased the use of tools and experientials engaging the subjective zone of "inside-out" experience (McCall, Lombardo & Morrison, 1988). This is the subjective, co-constructed territory of personal and shared experiences, identity, story-telling, myth, imagination, curiosity, beliefs, assumptions, visions, and faith – the elusive yet vital channels of the human soul and spirit (Kolb, 2014; Palus & Horth, 2002; Bunker, 1997; McCarthy, 1996; McAdams, 1988; Schön, 1983).

We have selected *Quick Tools* and methods here (Figure 6) that our colleagues and clients have found to be useful in a variety of contexts (Palus, Harrison, & Prasad, 2015; Palus & McGuire, 2015; McGuire, Palus, & Torbert, 2007).



I. Understanding Leadership Culture	Overview, research papers, case studies, Leadership Essentials
II. Discovering Leadership Culture	
a) Quick Tools for Inquiry	- Culture Walkabout tool - Storytelling tool - DAC Assessment tool - Six Box tool
b) Quick tools for Assessment	- Leadership Culture Assessment (individual interaction) - Leadership Culture Indicator (organizational overview) - Leadership Culture GAP (one page snowman) - Strategy Line-Up - Team Workstyle continuum - Transformations (Explorer)
c) Quick Tools for Dialogue	- Dialogue tool - Fishbowl tool - Putting Something in the Middle tool - Explorer tools (Visual, Metaphor, et al.)
III. Developing Leadership Culture	Overview: the arts and principles of development; service connections to CCL; Evaluation Guide: measuring effectiveness

Figure 6: The leadership culture *Quick Tools* box

The *Quick Tools* themselves, with common formats that explain Background, Purpose and How to Use, are simplified, practical, self-paced and user-friendly. These Leadership Culture *Quick Tools* are arranged by utility, and designed for discovery-based inquiry and exploration, strategic assessment for development, and deep dialogue for learning and development. For example, here we describe a few core *Quick Tools* for assessment of teams and organizations.

The vertical model is itself a useful facilitation. For example, a few executives informally (or a group formally) are presented a *Leadership Culture GAP* tool, a one page visual of the Snowman model, with clusters of descriptive indicators for each of three stages/states. Participants first individually and then together assess where their leadership culture(s) tend to be *embedded*, and where their strategy *requires* them to grow toward to face their challenges and realize their future vision and goals. In this *Quick Tool* They begin to take culture and its potential transformation as an object of attention and intention.

An organizational level version of the Snowman Model is the *Leadership Culture Indicators* tool, and provides fifteen specific indicators (items), arranged across each of the three stages. These items are distributed into three organizational categories of systems, engagement and learning. For example, in the systems (belief/practice) item for information, *need to know* characterizes the dependent-conformer culture whereas *want to know* the independent-achiever, and *shared openly with all* reflects the interdependent-collaborator leadership culture. This is typically used in poster form in the middle of a group where the value is discernment and learning in the team dialogue. This assessment tool is often used during an early phase of discovery in the transformation process. Such tools can also be critical in formal evaluation work used in Time 1 and Time 2 fashion. This kind of mediated dialogue, with issues of culture "in the middle," is a form of sustained, first- and second-person inquiry and thus developmentally potent (Torbert, 2004).

We focus on group-level interpersonal interactions in the *Leadership Culture Assessment* tool. Using the seven leadership logics as indicative of culture when taken in aggregate, we created a second-person assessment and inquiry tool (a rubric) for a more detailed look at leadership culture. We have identified four interpersonal processes that showcase the action logics as "what people do together." Rather than seen as individual competencies, these four processes are a bridge between the individual and the culture, where the logics play out in most common leadership interactions: *feedback*, *conflict*, *decision-making*, and *risk-taking*. Derived from the Benchmarks 360 degree assessment research at the Center for Creative Leadership (Leslie & Fleenor, 1998) and from our case studies of interdependent leadership cultures (McCauley et al., 2008), these four interpersonal processes are a basis for first- and second-person assessment of leadership cultures. The map is used by groups, teams and organizations to self-assess their center of gravity and the range of logics present in their work, across teams, divisions and functions, as well as the leadership logics required as organizational leadership capability for future success.

We also have created a first- and second-person inquiry tool called Transformations™ (www.ccl.org/Transformations), a portable, inviting tool which depicts each action logic as a set of illustrated cards, plus a set of cards showing a variety of catalysts and landmarks of human transformation. Transformations cards are used to portray personal and/or collective life journeys by selecting cards portraying their past, present, and aspired futures for themselves, their colleagues, and their leadership cultures (Torbert, Herdman-Barker, Izard & Palus, 2018).

Conclusion

The world is changing faster than we can imagine. Human consciousness needs to keep pace and yet we are stumbling. It is no longer appropriate to only develop a few leaders who are in charge of things. Individual development must be transcluded by the intentional development of collective consciousness, in which both the autonomy of persons and the shared culture are honored and advanced. Leadership culture is, we believe, the ripe ground for this advancement. The whole world is hungry for positive change that simultaneously uplifts individuals, groups, organizations, and our communities and societies. Pick up the development tools, play with them, invent new ones, use them, share them, teach them. Everybody everywhere is in this together.

Creating Responsive Learning Environments to Develop Students' Reflective Capacity

Patric Wallin,[1] Jonathan Reams,[2] Sven Veine,[3] and Martha Kalvig Anderson[4]

Abstract: In today's society, rapidly changing conditions and expectations mean that students need to learn how to make reflective judgments, and there is a clear need to better understand how to create learning environments that scaffold student learning to make these judgments. Here, we explore the design of a learning environment that integrates an computerized scoring system into a large scale course to provide students with formative assessment of their cognitive complexity level. We discuss important aspects to consider when framing and integrating this technology and how the deployment allows for formative assessment practices in large scale courses found in today's education.

Keywords: Cognitive ability, higher education, learning environment, metacognition, scaffolding.

Introduction

In today's rapidly changing world, it is not enough for *higher education institutions* (HEIs) to only equip students with discipline specific knowledge and skills (McAleese et al., 2013). HEIs should support students in becoming *lifelong learners* that can both adapt to and actively shape the society of the future (Schuetze, Slowey, Schue, & Slowey, 2015). Therefore, it is important to

create learning environments where students are empowered to take control of their own learning and engage in *self-regulated learning*, while at the same time receiving the necessary support to move forward (Pintrich & Zusho, 2007). Students need to learn how to face complex challenges and make judgments that take into account a multitude of dimensions, often with incomplete and conflicting positions (Barnett, 2004). These types of *ill-structured* or *wicked problems* (Brown, Harris, & Russell, 2010) require students to make *reflective judgments*. As King and Kitchener (2004) put it: "Reflective judgments are initiated when an individual recognizes that there is controversy or doubt about a problem that cannot be answered by formal logic alone, and involve careful consideration of one's beliefs in light of supporting evidence" (p. 6).

Students' capacity to make reflective judgments is closely linked to their level of *cognitive* and *epistemological complexity*, which can be conceptualized using *cognitive developmental models* that describe the progression through different stages from early childhood, through late adolescence and into adulthood (Hofer & Pintrich, 1997). For HEIs to help students increase their capacity for and quality of reflective judgments and become self-regulated learners, there is a clear need to better understand how to create *learning environments* that explicitly support the development of students' underlying cognitive and epistemological complexity and are conducive for growth into what Magolda and others call a *self-authoring epistemology* (Magolda & King, 2004). Within this field of research, two key aspects of the learning environment have been identified: the application of cognitive developmental models and *formative assessments* (Clark, 2012; Nicol & Macfarlane-Dick, 2006).

One way to create these kinds of learning environments is to integrate *Lectical Assessment*s into courses to provide students with the necessary individual formative assessment and support (Dawson, 2002; Dawson, Commons, & Wilson, 2005). The Lectical Assessment System (LAS) is a domain independent system for measuring cognitive complexity on Fischer's (1980) skill scale (Stein & Dawson, 2011) and is based on intensive studies of the pathways through which individuals build understanding and skill in specific knowledge areas (Dawson & Wilson, 2004). The scalability of Lectical Assessments has been limited due to the amount of training required to certify scorers and the human labour involved in scoring. However, the recent release of the *Computerized Lectical Assessment System* (CLAS) has altered this situation (https://lecticalive.org/demo/). The development of CLAS, as a fully automated system that provides developmental scores, enables the scaling of Lectical Assessments and facilitates their deployment within formative assessment practices in higher education settings.

Given the recentness of this development, there are currently few design examples showing how this type of computerized domain independent scoring system can be utilized for formative assessment of cognitive complexity can be used in higher education learning environments. In this study, we explore possibilities for designing a responsive learning environment based on Lectical Assessments scored with CLAS, with the overall goal to support students in the development of metacognitive capacity and reflective judgment. Grounded in the theoretical context of CLAS, we describe the exploratory deployment of the system in a master level course. The aim for this study is two folded. First, we want to get an idea about the range of students' scores within the course population and examine these scores in relation to the cognitive task complexity and implicit expectations of the course. The second aim was to investigate the possibilities to use the reports generated by CLAS to aid in the design of customized learning activities. In this way, this paper provides a reference point for researchers and academic practitioners in conceptualizing, designing, and creating CLAS supported responsive learning environments.

Theoretical Background

In connection with the emphasis on *student-centered learning* in higher education, self-regulated learning has become a central construct to describe effective academic learning (Butler & Winne, 1995). Pintrich and Zusho (2007) define self-regulated learning as situations where students: "….set goals for their learning and then attempt to monitor, regulate, and control their cognition, motivation, and behavior, guided and constrained by their goals and the contextual features in the environment" (p. 741).

In this context, it is important to recognize that students will not automatically become self-regulated learners in student-centered learning environments. Indeed, as pointed out by English and Kitsantas (2013): "For many students, the [self-regulated learner] role conflicts with deeply ingrained habits they have developed through more familiar classroom experiences, in which they have been passive recipients of knowledge" p. 129).

Self-regulated learning emphasizes knowledge as something that students actively co-construct, which requires them to become authors of their own learning and development, through what Kegan (1994) and later Magolda (2007, p. 69) call *self-authorship*: the internal capacity of a student to define his/her own belief system, identity, and relationships. It is therefore important that HEIs aim at creating learning environments that actively support the development of a *self-authoring mindset* (King & Kitchener, 1994; Magolda, 1992) throughout all their courses, while taking into account students' personal departure points. Educators need to help students to develop intellectually and become authors of their own learning and development. In the following two sections, we will situate our work within different strands of previous theoretical and empirical research; first epistemological beliefs, metacognitive and reflective skills and second, formative assessment and cognitive developmental models.

Epistemological Beliefs, Metacognitive and Reflective Skills

Epistemological beliefs are the beliefs we hold about the nature of knowledge and how we can know things (Hofer, 2001). Developing students' ways of thinking about knowledge and knowing is a key objective of higher education and at the core of students' ability to engage in a self-authoring mindset, as they are foundational for how students use and develop their skills. As Muis (2007, p. 173) proposed, epistemological beliefs: 1) constitute one component of the cognitive and affective condition of a task; 2) influence the standards students set for their goals; 3) serve as inputs to metacognition; and 4) are subsequently influenced by the students' development in self-regulated learning and self-authorship.

Early work in understanding the epistemological development of college students was undertaken by Perry (1970; 1999; 1981) who made extensive studies of epistemological growth in students. His research generated a stage model that went from absolutist perspectives of truth being a form of right or wrong, to relativist perspectives where conflicting versions of "truth" are to represent legitimate alternatives and a nuanced perspective of right and wrong. Perry's original intent was “a purely descriptive formulation of students’ experience,” rather than a “prescriptive program intended to ‘get’ students to develop” (Perry, 1981, p. 107). His work has been further extended in the domain of student services by Magolda (1992, 2007, 2008) who focused on how educational environments and experiences could be conducive to growth into self-authoring epistemologies.

Empirical studies have shown that epistemological complexity differs among students, and King and Kitchener (1994), as well as Magolda (1992), pointed out that the majority of first and second year students at HEIs are not engaging in self authorship and not all of them will develop this capacity by the time they leave HEIs. Given the age at which the majority of students enter higher education, it is natural that they come with a *socialized mind*, as achieving this order of consciousness is a major task during mid to late adolescence (Kegan, 1994). As characteristics of this stage, they subjugate their ego desires to the imperative of interpersonal relationships (King & Kitchener, 1994; Magolda, 1992), and look to authority figures like teachers to provide relevant knowledge and information. Kegan’s (1994) research has estimated that two thirds of the adult population operate from this (or an earlier) epistemological structure and have yet to achieve a fully self-authoring mindset. In a self-authoring mindset, there is a more mature and self-directed approach to using knowledge that enables a greater freedom and scope of behaviors where one is not subject to interpersonal relationships, but considers them in relation to internally driven values. Furthermore, empirical studies suggest that students’ average epistemological complexity is interrelated to the discipline they are studying (Paulsen & Wells, 1998). There are studies showing that students tend to hold more naïve epistemological beliefs in fields such as mathematics, science, and engineering, which could be seen as an attunement to the culture and teaching in these fields with a strong emphasis on facts, principles, and procedures presented in a dualistic mode (Felder & Brent, 2004; Wankat, 2002).

Students’ epistemological beliefs are deeply interdependent with their metacognitive and reflective skills (Muis, 2007). These skills are concerned with the processes by which students reflect upon their own learning, what learning means to them, dissecting their own thoughts, thinking about in what way they know something, arguing with themselves about possible alternatives, and thinking about how their experiences will shape their future (Gall, Gall, Jacobsen, & Bullock, 1990). Student-centered education both requires and stimulates the development of metacognition, but it is important that teachers provide the necessary scaffolding for students to enable them to develop over time (Handelsman, Pfund, Lauffer, & Pribbenow, 2005). While certain epistemological beliefs can limit the use of metacognitive and reflective skills, e.g. Dweck’s (1995) notion of the importance of attitude towards learning of either a fixed or a growth mindset, specific skills also offer an entry point to become aware of one’s own beliefs and develop a self-authoring mindset (Kegan, 1994). It is through learning and training metacognitive and reflective skills that students can advance their epistemological complexity level within the learning environments and support provided by HEIs (Wallin & Adawi, 2018).

The students’ pathway towards a self-authoring mindset emphasizes the development of skills for questioning beliefs, in particular the ability to make reflective judgments in relation to values, in order to determine if they are primarily coming from external sources or are one’s own (Wyn, Cuervo, & Landstedt, 2015). Shifting to an emphasis on skill, rather than a focus on the self or ego as a centralized meaning making system, enables the notion of self-authorship to be operationalized and its development scaffolded in learning environments at HEIs. In Fischer's *dynamic skill theory*, the core concept of skill is defined as "the capacity to act in an organized way in a specific context. Skills are thus action-based and context specific" (Mascolo, Fischer, & Lerner, 2010, p. 321).

With this in mind, it is important to realize that there is mounting evidence that metacognition as a skill needs to be learned – it is not something that all students carry with them when entering higher education (Wedelin & Adawi, 2014). This holds also true for reflection, which not all students will engage in on their own (Wallin & Adawi, 2018). Therefore, the development of metacognitive and reflective skills should be an important goal of higher education, as these skills are closely linked with the students' ability to plan, monitor, regulate, and evaluate their own learning (Bråten & Strømsø, 2005; Butler & Winne, 1995; Clark, 2012). HEIs need to support students' skill development in order to help them to become lifelong, self-regulated learners (Pintrich & Zusho, 2007).

Formative Assessment and Cognitive Developmental Models

Given that these metacognitive and reflective skills, described in the previous section, are central to the goals of higher education, the question becomes on how to support students in achieving them (Boekaerts, Pintrich, & Zeidner, 2000). To answer this question there is a clear need to better understand how to create learning environments that explicitly support the development of underlying cognitive and epistemological complexity and are conducive for growth into such a self-authoring epistemology (Magolda & King, 2004). Within this research, two important aspects of the learning environment have been identified: formative assessments and the application of cognitive developmental models (Clark, 2012; Nicol & Macfarlane-Dick, 2006).

In general, formative assessment supports students during the learning process by providing them with feedback on their performance and aims at helping students to reach their full capacity (Yorke, 2003). In contrast, summative assessment focuses on outcomes and the main question is to what extent students have reached the learning objectives (Clark, 2012). Formative assessment aims at helping the students to learn, and in this way is closely linked to scaffolding, a process described by Bruner (1973) as a practical approach to making use of Vygotsky's concept of the *zone of proximal development* (ZPD). Scaffolding is a teaching approach, where students learn through the interaction with a knowledgeable person that helps them in their development process and gradually reduces their support as the student becomes more independent (Wood, Bruner, & Ross, 1976).

On this basis, Nicol and Macfarlane-Dick (2006, p. 199) argued that ´*in higher education, formative assessment and feedback should be used to empower students as self-regulated learners*.´ However, one large challenge with implementing formative assessment widely at HEIs is the time demand it brings to teachers, as they should follow up all students individually and scaffold their development (Clark, 2012). In addition, the move towards student-centered learning environments and inductive teaching methods means that students work more and more independently, which limits students' direct interactions with teachers and constrains the possibility for formative assessment and scaffolding from the teacher (Clark 2012).

One way to overcome these limitations of formative assessment practices is to design responsive learning environments that scaffold student development on an individual basis. The CLAS version of the *Lectica Reflective Judgment Assessment* (LRJA), like other Lectical Assessments, was built specifically to support individualized instruction of this kind by providing diagnostic information that helps instructors and students themselves to identify their individual learning edge, or ZPD. Lectical Assessments can perform this function because each of them is informed by extensive primary research into the development of a given assessment target construct. This research involves the use of methods that build on a long history of research in the field of cognitive development, beginning with Baldwin (1895), followed by Piaget (1954, 1970), Kohlberg (1969, 1975), and Fischer (1980). The learning model and developmental scale that most directly inform the methods employed to build Lectical Assessments are Fischer's (1980; Fischer & Bidell, 2006; Fischer & Yan, 2002; Mascolo et al., 2010) dynamic skill theory and *skill scale* (Stein & Dawson, 2011).

Lectical Assessments measure the developmental level of understanding demonstrated through assessment responses (Stein & Dawson, 2011). Numerical scores (called Lectical Scores) provided with Lectical Assessments are calibrated to Fischer's (1980) skill scale. The hierarchical complexity of cognitive tasks mapped by Fischer's skill scale describes how sensory motor actions develop from single actions, through mappings into systems and even systems of systems of actions. The latter are 'chunked' into single representations, which then also go through a similar set of stages before cognitive processes move into the tier of abstractions. While Lectical Assessments are typically scored by trained humans, CLAS is a fully automated system that provides developmental scores that agree with human scores 85% of the time within one fifth of a level. This rate of agreement is comparable to human inter-rater agreement (Dawson, 2017). In contrast to other text analysis systems that measure and quantify simple text parameters like vocabulary and punctuation, CLAS algorithms are based on deep studies of learning and development that involves a blend of human expertise and analytics. At the core of CLAS is the Lectical Dictionary that provides a constantly evolving taxonomy of the development of meanings. At the moment, the dictionary contains 230,000 words and phrases that are assigned to a Lectical Phase (1/4 of a Lectical Level). The CLAS system uses the dictionary to measure the hierarchical complexity of the text provided by the users and measures growth along the Lectical Scale. While the dictionary and CLAS algorithms do not learn on their own, the systems is developed through a human/machine collaboration, where trained human analysts curate CLAS and CLAS makes suggestions based on its existing algorithms.

College students who have taken the LRJA generally perform in the range of 10.5 to 11.4 on this scale, which represents the range from the middle of abstract mappings through the middle of abstract systems. While CLAS and human scorers are able to provide very precise Lectical scores on a given assessment performance, it is understood that the range of performance variability means that for practical purposes, formative feedback to test takers is designed to address Lectical phases within ¼ of a level of a test takers score. This range can be considered to be within their ZPD and thus instructions and instructional material, in order to meet achievable learning goals, should be designed to be no more than 0.25 above their score. The typical rate of growth in the college years is around 0.13 of a level per year (Stein, Dawson, Van Rossum, Rothaizer, & Hill, 2014). Research on city workers using Lectical assessments as part of a training program were found to have growth of 0.18 – 0.27 over a four to nine month period (Stein et al., 2014).

The CLAS / demonstration version of the LRJA employed in this research provided students with a report that covered three areas: 1) the Lectical Score from CLAS, 2) a description of the kind of reasoning typically associated with this score and a description of typical reasoning at the next quarter of a level together with a learning activity that involves a comparison of these two ways of thinking with the students' responses, and 3) a description of the students' likely learning edge (or ZPD) accompanied with a learning activity targeting either deliberation skills or skills for working with evidence (Stein et al., 2014). The learning activity in the report is based on the individual growth edge of the student and specific tasks are outlined for how to go forward in a *Virtuous cycle of learning* (VCoL) (Stein et al., 2014). VCoLs are a generic adaptation of various cyclical learning models such as Kolb's (2014, p. 50) experiential learning cycle. It involves; 1) setting a goal (usually informed by some aspect of a formative developmental assessment), 2) seeking information related to that goal at a ZPD relevant level of cognitive complexity, 3) applying this information to real life situations for practice, 4) reflecting on what happens during the application of this new information and 5) resetting the goal based upon the reflections in step 4.

To our knowledge, there is no published research to show how this kind of computerized system and the automatically generated individualized skill development sequences can be made context specific within a course. Others have used different types of intelligent tutoring systems, but these systems are often task specific and do not offer students with information about their developmental level of understanding and how they can improve it. For example, Murray & Arroyo (2002) used Animalwatch as an intelligent tutoring system that provides students with progressive hints when they enter incorrect answers to word problems. CLAS on the other hand provides much more advanced information and therefore consideration of the relationship of these sequences and skill building activities to course specific learning objectives in higher education learning environments need to be carefully addressed. Thus using the LRJA report content as a starting point, we explored the possibility of working with students to develop more personalized learning activities tied to students' growth edges and in relation to a specific course context, as we will describe and discuss below.

Context

The *Experts in Teamwork* (EiT) course was selected as a pilot course to implement the use of the CLAS version of the LRJA for four reasons: its interdisciplinary nature, its emphasis on experienced-based learning, its size, and its organizational support structure. EiT is an interdisciplinary, and to some extent an intercultural, team-based 7.5 ECTS (European Credit Transfer and Accumulation System) course at the Norwegian University of Science and Technology (NTNU), with the aim of developing students' interdisciplinary and intercultural collaborative competencies (www.ntnu.edu/eit). By virtue of being mandatory in almost all five-year undergraduate and master programs, EiT is one of NTNU's largest courses with more than 2300 students each year. Due to a recent fusion between NTNU and several colleges, NTNU has become the largest university in Norway and the EiT course will expand to include approximately 3000 students unevenly distributed in three Norwegian cities by the year 2021.

The structure in EiT is that a teacher provides a general theme suitable for an interdisciplinary working approach that up to 30 students can select. These groups of students organized by themes, called villages, each have a teacher who is responsible for structuring and guiding the teams' work process, as well as providing the necessary thematic content that the students need. In total, there are about 90 teachers teaching in EiT each year, representing all faculties. The course is coordinated centrally by academic developers and staff from the EiT Section who organize and administer the villages in cooperation with the faculties. To support the teachers, basic training in the experience-based approach used in EiT is given through seminars and lectures, as well as teaching and learning material for all students that they can use within their villages, including a *Book of Reflections*. In addition to a teacher, or in EiT terms, village leader, each village has two learning assistants that facilitate the teams. These are students employed on a part-time basis that receive training in observing team behavior and asking open-ended questions, and conducting reflection and feedback exercises. The learning assistants' role is to initiate reflections, highlighting aspects of the team dynamics that may be less evident to the team itself, thus giving the team an opportunity to discuss and become aware of previously hidden dynamics. It is important to point out that the teams retain autonomy on what inputs from the learning assistants they want to consider, evaluate, and use to change their team processes, and what actions to take.

Within each village, the students are put in interdisciplinary teams of 5-7 students to work on a self-defined project coupled to the village theme. With all of NTNU's faculties represented, a team may include students from medicine, natural science, engineering, computer science, social science, humanities and/or economics. As a result, students will expand perspectives on their disciplinary knowledge through their encounter with skills from other disciplines.

The desired learning outcomes in EiT are strongly focused around the students' ability to become aware, reflect upon, and improve their interdisciplinary team work, dynamics, and processes. Throughout the project work, the students develop these teamwork skills by analyzing, on their own and together, the situations that arise as the team works on their interdisciplinary project. Based on their understanding of situations, the students reflect on how they communicate, plan, make decisions, solve tasks, handle disagreements and relate to academic, social and personal differences. Through individual and team reflection activities, as well as the application of relevant concepts and fundamental group theory, the student teams can become aware of their group dynamics and learn how to collaborate in interdisciplinary teams by taking actions to improve their teamwork. In this way, EiT aims at providing students with a learning environment that stimulates the development of reflection and metacognitive skills, as well as overall intellectual development and personal growth.

Assessment in EiT has both formative and summative elements. The continuous interactions between the students, learning assistants, and teachers allows direct feedback and individualized formative assessment that is targeted towards students' current level of cognitive complexity. However, there are limits to the depth and amount of formative assessment that the learning assistants and teachers can provide, as we will discuss later. In addition to the formative assessment, the student teams are assessed on both their project work, as well as their analysis and reflection of their group dynamics and team development processes. The summative assessment is based on a project report and a process report, each worth 50% of their final grade. There are no individual grades; each team is given a grade as a whole. However, all students are required to present an evaluation at the end of the course that focuses on their individual and team development during the period of the course.

Mapping Students' Reflective Capacity

The large scale of the EiT course, in combination with the disciplinary diversity of students provides a challenging situation to support and scaffold individual students' development. This is especially true in the area of reflection and reflective judgment, where students come with a range of different experiences and training. During the time EiT has been offered, a number of anecdotal stories emerged related to perceived difficulties for many EiT students in understanding the reflection and group process components of the course. Taking this as a starting point, the CLAS version of the LRJA was used to map the range of LRJA scores among students. In addition, the cognitive task complexity of the EiT Book of Reflections given to students as a course resource was assessed to get an idea about the match between the students' level and the level of the instructional material.

In this pilot study, the aim was to explore the general suitability of CLAS and develop strategies to frame the system for the students. Therefore, students in selected EiT villages were invited over the last two years to participate in taking the LRJA demo and try out learning activities based on their Lectical score and designed to complement the Lectical reports they received. The students had free access to the system and could do the assessment at any time. Neither the teachers nor the researchers had access to the students' scores or reports directly from Lectica, but students were asked to submit their reports to the researchers in order to adapt the use of CLAS and associated learning materials in the future. Over the two years of this research project, 76 students sent in their reports and scores as input into mapping the range of reflective judgment skills among EiT students (26 in the first year, and 50 in the second year).

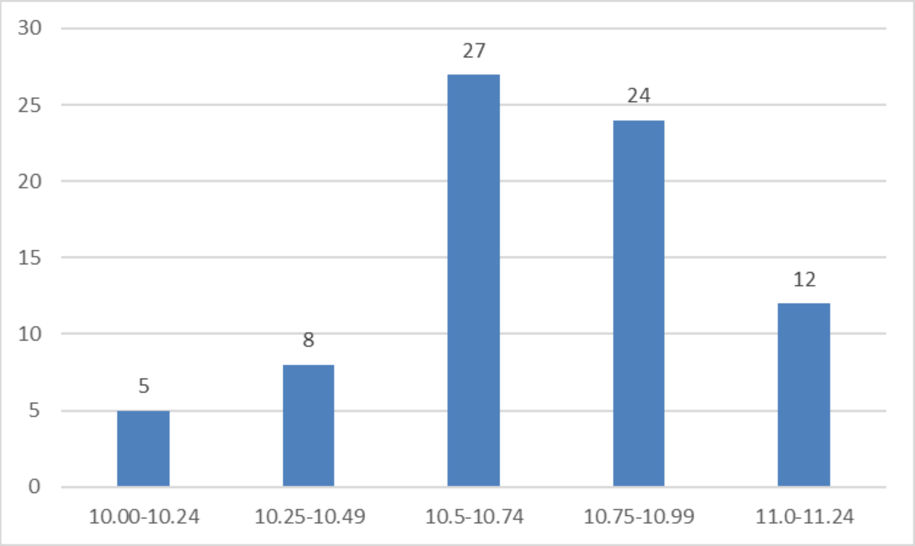

Figure 1. Scores on CLAS version of the LRJA.

The scores from the students ranged from just below 10.2 up to 11.24, as shown in Figure 1. These results indicate that the sample of students participating in the EiT mapping exercise generally fell within the normal range of distribution, which is 10.5 – 11.4 for college students. This pilot study showed that it is possible to get information about the complexity of reflective judgment in a diverse student population that is highly relevant for the course, yet otherwise difficult to obtain. While a normal distribution curve is one aspect, it can also be that different subject areas promote the development of reflective judgment as a skill more than others do (Felder & Brent, 2004; Wankat, 2002). With a limited number of students and a potential self-selection bias that might affect the score distribution, it is however not possible to explore this area more at the moment.

While from a research perspective information about the student population is interesting, detailed information and statistics are primarily of interest in supporting the design process of a responsive learning environment. Here, it is important to point out that CLAS should not be used to stigmatize and judge students, but to enable teachers to provide individuals with the best possible support and scaffolding of their learning and development. The type of mapping described here can be viewed as a starting point, but the focus needs to remain on the individual students in the class.

One area where this type of student population mapping is of interest is in connection with the general design of instructional material that should support students during the course. We therefore chose to score the cognitive complexity of the EiT Book of Reflections, a central resource for the students in their development of reflective skills, with CLAS in order to get an idea of how well it matched with the students' level of cognitive complexity. The text from the EiT Book of Reflections scored 11.2. (Note that the original text is in Norwegian, and the text we scored was translated by one person, which could have contributed to the uniform score across different sections of the book, which were written by different and collaborating authors in Norwegian. As well, there is a larger issue with how different languages construct meaning over time and that building a similar Lectical dictionary in other languages has not yet been attempted). This means that the majority of students in this small sample scored between 0.2 and 0.7 of a Lectical level below the material meant to support them. A gap of 0.25 can be considered to be within their ZPD and the types of activities and explanations provided in the EiT Book of Reflections can be seen as providing an optimal scaffolding and learning activities for these students. For the students scoring in the same range as the Book of Reflections, it is likely that the reflection skills described in the book are already natural cognitive processes. They would likely be able to understand and practice those activities as described without extra effort.

However, for those students whose LRJA scores have a gap from the EiT Book of Reflections of more than 0.25, it could be that the expectations and activities described are outside of their ZPD. This can arise from how constructs used at higher Lectical levels of complexity 'chunk' lower complexity constructs, or have internalized them as implicit, or taken for granted. Thus there can be a lack of sufficiently explicit use of a wider range of constructs that are necessary to provide access for all students to the instructions provided. This could contribute to a number of issues arising for these students, as reported in anecdotal evidence from learning assistants and teachers over time. It could be that they read and discuss with classmates the reflective activities and believe they have understood them, when key aspects implicit in the expectations from EiT may actually be misunderstood. It could also be possible that students read the descriptions and activities in the EiT Book of Reflections and feel frustration at not understanding them. This frustration could contribute to critical or outright negative perceptions and evaluations of the course, giving up on trying out suggested activities, or other forms of reaction to being asked to perform cognitive tasks beyond their ZPD in this skill domain.

In more general terms, it is clear that the general instruction material works very well for some students, but will be more problematic for other students. In the case of the EiT Book of Reflections, it is likely that the cognitive complexity level it implicitly presents is outside of the optimal ZPD for a considerable part of the student population. This mismatch can be mediated through the support from the learning assistants and teachers, but does not provide optimal base conditions for learning. Grounded in our mapping exercise and the potential challenges associated with a mismatch between students' and instructional materials' cognitive complexity levels, we will in the next section discuss our exploratory experiments with the design of instructional material that could address this potential gap. Our aim was how to provide individual students with the necessary support suited for their current level through the design of a more responsive learning environment.

Design of a Responsive Learning Environment in EiT

In the previous section, the variation in students' scores in relation to the level of the instructional material was discussed. In this section, the design of a more responsive learning environment based on the CLAS version of the LRJA in combination with new instructional material will be explored and discussed. The focus in this pilot study lies in using CLAS to support teachers and learning assistants in their ability to scaffold and support student learning. By providing a tool that enables individualized formative assessment that is targeted towards students' current level of cognitive complexity, it is possible to create a more responsive learning environment. Figure 2 provides an overview of the different types of learning materials designed within this study to create a supportive learning environment.

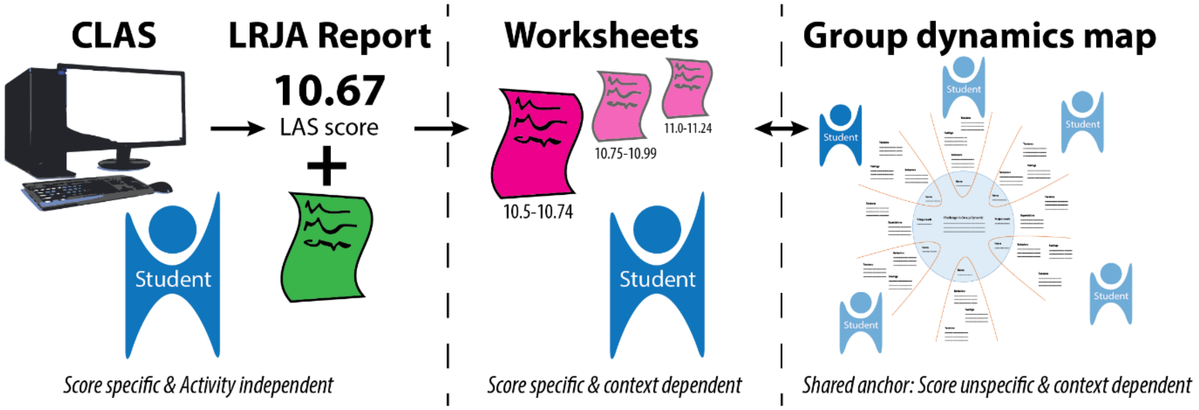

Figure 2. Schematic overview of the CLAS based responsive learning environment with the different learning materials.

Formative assessments that scaffold students' learning and development can be divided into two categories: general formative assessment and context dependent formative assessment (Evans, 2013). General formative assessment is independent of a course's format and content, and provides more general help on how a student can improve. The CLAS version of the LRJA report falls in this category of general formative assessment and the VCoLs associated with it support the students in a broad way, independent of the EiT context. While the information in the report and the VCoLs themselves are useful, as a kind of meta-cognitive process of making the character of their own thinking an objective description that they can then reflect on, it does not necessarily help the students achieve their context specific learning goals within the course. For the current project, the broad nature of these VCoLs provided in the LRJA reports would require significant investment from students in order to adapt them to the more specific contextual requirements of the EiT course.

Therefore, a special interest in this study was on the development of context dependent formative assessment. To bridge the gap between the context specific learning goals in EiT and general LRJA report, a set of worksheets were designed in an attempt to make the learning activities more directly related to aspects of the learning requirements in the EiT course, and increase the perceived relevance of the LRJA. This context dependent formative assessment more easily helps students to realize the value of the LRJA, as it resonates directly with something that they are working on and situates their learning into their current experience (J. S. Brown, Collins, & Duguid, 1989).

The learning material that was designed particularly for the EiT course consists of two parts, a group dynamics map that works as a shared anchor for the students, and context specific VCoLs. The group dynamics map (Appendix A) is a score independent document, which invites students to identify other team members in relation to their behaviors and the feelings and tensions they might experience. It supports students in capturing their current understanding of the group dynamics and how their understanding changes after working with the VCoLs. While the students might have different scores and work with different VCoLs, the map provides the team with a shared document to exchange ideas and develop as a team. The map also anchors the LRJA report and VCoLs to the course by making the use of it explicitly relevant to the desired learning outcomes of increased awareness, reflection, and suggested improvements in the areas of teamwork and group dynamics.

In the first year of this study, a detailed series of context specific VCoLs were designed to closely match the specific LRJA demo reports the students received. (Assessment takers would receive a report based on their Lectical level and feedback focused either on *thinking and deciding*, or on *working with evidence*). The aim was to provide a bridge from the LJRA demo reports to the EiT course requirements and activities. Feedback from the villages and students trying these out was that the process was overly complex and that the links between the LRJA reports, worksheets we provided and their course activities was not clear enough.

This led to revising the set of worksheets and instructional materials in the second year of the study. This time, context specific VCoLs targeting the three predominant phases of student scores were developed and used (10.5-10.74, 10.75-10.99, and 11.0-11.24, also independent of the focus of the LRJA feedback on either *thinking and deciding,* or on *working with evidence*). By developing VCoLs with different cognitive complexities, most students were provided with material that fell within their ZPD . The VCoLs designed for the EiT course were structured around the same five steps as the general VCoLs: Target, seek, apply, reflect, and reset. An example of a worksheet can be found in the Appendix B.

On a content level, two different factors informed the design process, the learning outcomes of the course and the historical knowledge about common student experiences and challenges. By using both factors, the adapted VCoLs coupled material from the LRJA report with the students' activities more directly to the rest of the course than in the first attempt at this the previous year. The aim of these new worksheets was to provide students with methods to gain relevant information about other team members and how their interactions affected the group dynamic. The main adaptation was to take the information seeking phase, which was generally taken straight from the CLAS system, and adapting the application of it to how students could complete their reflection tasks as an individual. To help the students to learn about this and be able to reflect on their experiences, both individually and as a team, the worksheets were designed to make it easier for them to learn from their direct experience in the teams. From this, the students were invited to consider what elements of their individual reflections they might want to share with the team, as a way of contributing to the team reflection activities.

In this way, student learning and development was individualized through CLAS score dependent VCoLs and students on all levels get the optimal instructional material that could support their learning of reflective skills. At the same time, the group dynamic map acted as an anchor to keep the group together and facilitate processes in which all students could contribute to the team development.

Framing this type of next-generation assessment system is a key factor to be considered to develop new formative assessment practices and fully use the opportunities of computerized systems (Heritage, 2010). The advantage of using a computer based system is that students can take the assessment as often as they want and whenever they want (Bull, Quigley, & Mabbott, 2006). In addition, the use of the CLAS system is independent from the university and the students themselves choose if and when they want to share their scores with the teacher. This means that the students themselves stay in control of the whole process, which mediates risks described above (Nicol & Macfarlane-Dick, 2006). Within a responsive learning environment, the information gained from the LRJA can be used to help students take the next step and create learning opportunities that lie within their individual ZPD. As Shepard (2009) pointed out “it is the use of an instrument, rather than the instrument itself that must be shown, with evidence, to warrant the claim of formative assessment” (p. 33). The CLAS version of the LRJA needs to be seen, both by teachers and students, as an entry point for development and growth rather than as a summative assessment. Otherwise, the formative assessment dimension is compromised, and the assessment is seen as a high stakes test, associated with a potential negative impact on motivation for learning, especially for weaker students (Black & Wiliam, 1998). At the same time, the approach described here offers interesting opportunities for HEIs to provide teachers with the necessary tools to support students in their intellectual development.

Summary and Future Research

Overall, the design of responsive learning environments is facilitated by the development of technology solutions like CLAS. However, the skill in framing and integrating of this type of technology into specific learning environments is the decisive factor in the success of scaffolding student learning. It is through the careful and collaborative integration of technology between students and teachers that responsive learning environments can be created.

In this article, we have explored and discussed important aspects to consider when using technology to create responsive learning environments that aim to contribute to the development of self-regulated student learning. The described approach has significant potential to support students and scaffold their development. Supporting and scaffolding students’ development is difficult and demanding and this is especially true in large classes, where interactions between teachers and students are limited. Automated systems offer an interesting approach to this dilemma, but need to be balanced through social interactions and framing to minimize the risk of being perceived as summative assessment tools, high stakes tests, or control instruments. While the numerical score provided by CLAS can be helpful to get a better understanding of the overall student population, it is in itself of little help for the students. It is through using the score to inform the design of ZPD and context specific skill building activities that students' learning can be scaffolded efficiently.

Based on the experience and insights that we have gained from this pilot application of the CLAS version of the LRJA in the EiT course, we plan to take further steps to integrate this information about the range of reflective skills students bring to the EiT course with more robust learning activities. In the future, we want to look at two different research directions. First, we will continue to study the effects of responsive learning environments created with the CLAS system and explore students' experiences, development, and reflective capacity in more detail. Within this strand of research, we will also look at possibilities to use CLAS in other courses and further consider the framing of this type of system within the higher education context. In light of the current emphasis on digital tools and formative assessment, we think that CLAS can make an important and interesting contribution in the future, but more research is clearly needed to better understand how to use this type of system in higher education to its full potential.

The other research direction that we want to explore in the future is to combine utilizing dynamic skill theory and the knowledge gained from using the CLAS system with other ways to create responsive learning environments. In particular, we are going to collaborate with a broader group of colleagues on creating a developmentally informed sequence of reflective prompts for students to use in conjunction with their daily journaling activity. For this, we will utilize Snowden's (2010; 2007) SenseMaker platform to enable students to log their journal entries into an online platform, either through a web browser, smartphone or tablet. Students will then be invited to reflect on their entry using the sensemaking process of placing a marker in relation to a triad of three equally weighted signifiers. We will design a sequence of these signification triads keyed to what we understand in relation to the types of constructs that will be in the ZDP of different students. Thus all students can use the same platform, but find the reflective prompts that best fit their learning needs. One advantage of the SenseMaker platform is its flexibility and the fact that it can be adapted more easily to the specific context, as well as to the students' native language. Comparing CLAS and the SenseMaker platform will allow us to gain a deeper understanding of responsive learning environments, their creation, and the underlying learning and development processes stimulate by this type of learning environment.

In summary, we believe that the general aspects of the approach explored and discussed here are highly relevant for many courses in higher education. Using computerized systems in the manner described here can enable HEIs to provide the necessary formative assessments to scaffold students' development in many domains. The possible adaptation of CLAS to a broader range of skill domains is one aspect of this. More broadly, as an essential factor in later success in society, HEIs can help students towards a self-authoring mindset even in large scale courses commonly found in today's mass education by creating responsive learning environments.

Acknowledgements

We would like to thank all the students who took part in this study and together with us, designed and explored EiT as a responsive learning environment. Further, we would like to thank EiT academic staff for fruitful discussions and Lectica for making CLAS available. We would also like to thank Dr Theo Dawson for her helpful comments and suggestions during the drafting of this paper.

Note: The researchers of this study have no financial interest in Lectica as an organization and there is no conflict of interest. The work in this research did not receive any specific funding, but the researchers have fully funded positions at NTNU.

VCoL Worksheet A

10D Deliberation

Take your group dynamic map and fill in the parts that you already have some ideas about.

Goal: *To fill out parts of your group dynamic map as a rich picture of a system.*

Seek: Watch this video suggested in your report: https://www.youtube.com/watch?v=-sfiReUu3o0 (12 minutes) Then watch this three minute video: https://www.youtube.com/watch?v=17BP9n6g1F0 .Finally, this seven minute video: https://www.youtube.com/watch?v=lhbLNBqhQkc

Make notes on what you learn about systems thinking.

Apply: Examine your group dynamic map and apply your new knowledge about systems thinking to make connections or patterns explicit.

Make any changes to what you noted earlier about specific individuals or contexts.

Reflect: What changed in terms of what you entered into your group dynamic map about different team members? About connections between them? Or between them and the project or village?

Were you surprised by anything you learned?

Write down what you learn from doing this activity in your personal reflection book. Also write down any new insights you get from these dynamics or patterns to the map. Is anything clearer now? Is something new unclear? What would you want to share with the group?

ReSet: Given what you have learned from this process so far, how might you further fill in other parts of your group dynamic map? What else can you clarify, the next time you try it? How might you adjust how you contribute to the group?

Love in a Time Between Worlds: On the Metamodern "Return" to a Metaphysics of Eros

Zachary Stein[1]

Abstract: Modernity is based on a critique and abandonment of premodern forms of metaphysics, while postmodernity has only deepened critiques of metaphysical truth claims further. This has created a novel historical situation in which a planetary society revolves around the absence of a shared metaphysics. The vacuum of meaning at the core of postmodern societies has resulted in a sense of exhaustion and alienation, a state uncomfortable enough to initiate a metamodern "return" to metaphysical speculation. I argue in favor of adopting metamodern metaphysical characterizations of the human based on an understanding of love as a transpersonal universal force akin to gravity. Philosophers have long called this force *Eros* and have placed it at the center of the human experience. Charles Sanders Peirce marks the beginning of a new method for practicing metaphysics, while at the same time offering profound insights into the cosmic dynamics of evolutionary love, or Eros. A century later, the ideas and practices of metamodern metaphysics remain in flux and on the margins. I explore how computer technologies and hyper-capitalist dynamics have inspired dark transhumanist speculations such as those of Nick Land. To counter the regressive and dystopian possibilities entailed by a "return" to metaphysics, I propose a form of cosmo-erotic humanism and discuss its implications through an exploration of the newly released book, *A Return to Eros* (Gafni & Kincaid, 2017).

Keywords: Charles Sanders Peirce, Eros, Integral Theory, Marc Gafni, metaphysics, metamodernism, Nick Land, political praxis, post-modernity, post-truth culture, sexuality and relationships, Tantra.

Introduction

Metamodern Metaphysics: Or Eros in the 21st Century

> Men [sic] have gained control over the forces of nature to such an extent that with their help they would have no difficulty in exterminating one another to the last man. They know this, and hence comes a large part of their current unrest, their unhappiness and their mood of anxiety. And now it is to be expected that the other of the two 'Heavenly Powers,' eternal Eros, will make an effort to assert himself in the struggle with his equally immortal adversary [Thanatos].
>
> – Sigmund Freud (1931/1961) Civilization and Its Discontents, p. 112.

The quote above was not in the first edition of *Civilization and Its Discontents.* Freud added this reflection to the conclusion of the 1931 edition as it was becoming clear that Germany was

SOME RIGHTS RESERVED

sliding towards fascism under Hitler’s rule. In making appeals to metaphysics (positing the eternal forces of Eros and Thanatos), Freud put a controversial finishing touch on the theoretical edifice of psychoanalysis. However, psychoanalytic metapsychology had always depended upon forces of nature beyond the human ego; the unconscious (the *id*) was conceived as if it were a force of nature within “me,” which was at the same time somehow “not me.” *Metapsychology* is a term used by Freud and others to describe the broadest and most reflective work a psychologist can do, which involves not just theorizing about the psyche, but theorizing about the structure of psychological theorizing itself. Freud would follow his metapsychological investigations where they led many other great psychologists (including Jean Piaget and James Mark Baldwin) into the realms of metaphysics.

This route from science to metaphysics is not unique to psychology. Investigations into the structure of theories in all fields of science eventually lead to deep metaphysical and ontological issues (Bhaskar, 1993). However, when psychologists begin to get metaphysical the implication is that humans themselves – the realities of our minds and emotions – are taken up into speculative heights, beyond what can be “proven” in any simple scientific way. Eros in particular has been repeatedly placed at the core of metaphysical characterizations of the human being. In this paper I explore some of the implications of taking a metaphysics of Eros seriously in the context of contemporary cultural and social crises. Today we are again seeing a fight played out between the eternal forces of Eros and Thanatos.

However, first I must demonstrate that it is even possible and appropriate to offer reasonable metaphysical characterizations of the human at all. The discipline of metaphysics is notoriously controversial and metaphysical claims are suspect in modern and postmodern discourse. Where modern scientists often critique the claims of metaphysics as unverifiable and thus untrue, postmodernists critique both science and metaphysics for making truth claims in the first place. Either way, to call an idea or theory “metaphysical” has become another way of saying it is unacceptable. Often this comes with some implication that the theory is a kind of superstition, which means metaphysics is taken not as an attempt to engage the truth but rather as a kind of covert power play or psychological defense mechanism. I argue the opposite: metaphysics is what saves us from a descent into discourses that are merely about power and illusion.

I am not arguing for a return to premodern forms of metaphysics, which were rightly overthrown by the modern revolutions in scientific methods and epistemology. What follows is “post-Kantian” and “post-metaphysical” in the Habermasian sense; it is what Charles Sanders Peirce and Roy Bhaskar call “scientific metaphysics.” I agree with those who argue that learning and the development of knowledge eventually lead to a “return” to metaphysics at a higher-level. I think a post-postmodern or “metamodern” revival of metaphysics is part of our historical moment (Freinacht, 2017 pp. 361-376). The term *metamodern* is used simply to describe the structure of what is emerging “after postmodernism;” it points out the new personalities, cultures, and theories that are able to critique and integrate the insights of both the modern and the postmodern. Believe it or not, there are metaphysical systems that survived postmodernism and popped out of the far end of the 1990’s with “truth” and “reality” still intact. These include *object-oriented ontology* and *dialectical critical realism,* among others. Metaphysics can be practiced after Kant and Darwin only by theorizing beyond what is thought of as acceptable in postmodernism and late-stage capitalism, as I discuss in the first section below.

It is worth working from Hanzi Freinacht's seminal book on metamodernism as a way to clarify what is meant by metamodern metaphysics. Here I offer a partial and augmented version of Freinacht's characterization of what philosophers must embrace under the emerging conditions of metamodern society (Freinacht, 2017 pp. 364-366):

METAMODERN VIEW OF SCIENCE

- To respect science as an indispensable form of knowing.
- To see that science is always contextual and truth always tentative; that reality always holds deeper truths. All that we think is real will one day melt away as snow in the sun.
- To understand that different sciences and paradigms are simultaneously true; that many of their apparent contradictions are superficial and based on misperceptions or failures of translation or integration.
- To see that there are substantial insights and relevant knowledge in all stages of human and societal development, including tribal life, polytheism, traditional theology, modern industrialism and postmodern critique. In another book, I call this the evolution of "**meta-memes**".
- To celebrate and embody **non-linearity** in all non-mechanical matters, such as society and culture. Non-linearity, in its simplest definition, means that the output of a system is not proportional to its input.
- To harbor a case sensitive suspicion against mechanical models and linear causation.
- To have "a systems view" of life, to see that things form parts of self-organizing bottom-up systems: from sub-atomic units to atomic particles to molecules to cells to organisms.
- To see that things are alive and self-organizing because they are falling apart, that life is always a whirlwind of destruction: The only way to create and maintain an ordered pattern is to create a corresponding disorder. These are the principles of **autopoiesis**: entropy (that things degrade and fall apart) and "negative entropy" (the falling apart is what makes life possible).
- To accept that all humans and other organisms have a connecting, overarching worldview, a great story or grand narrative (a religion, in what is often interpreted as being the literal sense of the word: something that connects all things) and therefore accept the necessity of a grande histoire, an overarching story about the world. The metamodernist has her own unapologetically held grand narrative, synthesizing her available understanding. But it is held lightly, as one recognizes that it is always partly fictional—a **protosynthesis**.
- To take ontological questions very seriously, i.e. to let questions about "what is really real" guide us in science and politics. This is called the ontological turn.

METAMODERN VIEW OF REALITY

- To see the **fractal** nature of reality and of the development and applicability of ideas, that all understanding consists of reused elements taken from other forms of understanding.
- To be **anti-essentialist**, not believing in “ultimate essences” such as matter, consciousness, goodness, evil, masculinity, femininity or the like – but rather that all these things are contextual and interpretations made from relations and comparisons. Even the today so praised “relationality” is not an essence of the universe.
- To no longer believe in an atomistic, mechanical universe where the ultimate stuff is matter, but rather to view the ultimate nature of reality as a great unknown that we must metaphorically capture in our symbols, words and stories. To accept the view of a world being newly born again and again.
- To see that the world is radically, unyieldingly and completely socially constructed, always relative and context bound.
- To see that the world emerges through complex interactions of its parts and that our intuitive understandings tend to be much too static and mono-causal. This is called **complexity**. It is the fundamental principle of not only meteorology but also of social psychology, where patterns (such as the “self”) emerge through the interactions of interrelated, interdependent **dividuals**.
- To accept the necessity of **developmental hierarchies** – but to be very critical and careful with how they are described and used. Hierarchies are studied empirically, not arbitrarily assumed.
- To see that language and thereby our whole worldviews travel through a much greater space of possible, never-conceptualized worlds; that language is evolving.
- To look at the world holistically, where things such as scientific facts, perspectives, culture and emotions interact (this form of interactivity is called **hypercomplexity**, because it involves not only many interacting units, but interacting perspectives and qualitatively different dimensions of reality, such as subjective vs. objective reality).
- To see that information and management of information is fundamental to all aspects of reality and society: from genes to memes to money and science and political revolutions.
- To accept an informational-Darwinian view of both genes (organisms) and memes (cultural patterns) competing to survive through a process of developmental evolution that involves negative selection (that disfavored genes and memes go extinct, but continue to exist as potentials).
- To see that Darwinian evolution depends equally on mutual cooperation and competition; that competition and cooperation are always intertwined.

METAMODERN VIEW OF REALITY Cont'd

- To see the dynamic interplay of the universal and the particular, where for instance humans in more complex societies become more individualized, which in turn drives the development of more complex societies where people are more interdependent and more universal values are needed to avoid collapse.
- To see that the world runs on **dialectic logic**, where things are always broken, always "stumbling backwards" as it were; that things are always striving for an impossible balance and in that accidental movement create the whole dance that we experience as reality. So the development of reality does have directionality, it's just that we are always blind to this direction; hence the metaphor of "stumbling backwards".
- To see that reality is fundamentally open-ended, broken, as it were, even in its mathematical and physical structure, as shown in Gödel's incompleteness theorem and in some of the core findings of modern physics.
- To recognize that potentials and **potentiality**, rather than facts and actualities, constitute the most fundamental or "more real" reality. What we usually call reality is only "actuality", one slice of an infinitely larger, hypercomplex pie. Actuality is only a "case of" a deeper reality, called "absolute totality".
- To explore visions of **panpsychism**, i.e. that consciousness is everywhere in the universe and "as real" as matter and space. But panpsychism should not be confused with animistic visions of all things having "spirits".

This list of ideas that characterize the new emerging metamodern syntheses and theories point in the direction of a particular kind of metaphysics. I am proposing that it is possible to reconstruct a metamodern metaphysis of Eros, which honors all of the above (and more), making it a viable framework for human self-understanding. Once the ground is cleared for doing a new kind of metaphysics, I then explore a metaphysical characterization of the human that is best described as *cosmo-erotic humanism*. This emerging metamodern metaphysics is the focus of work among a cluster of scholars including Marc Gafni, Barbara Marx Hubbard, Kristina Kincaid, Ken Wilber, Sally Kempton, Daniel Schmachtenberger, myself, and others in and around the Center for Integral Wisdom. In this paper I use the recent book by Gafni and Kincaid, *A Return to Eros* (2017), to scaffold a discussion about *reality, politics, and sex* from the perspective of cosmo-erotic humanism. These three topics (sex, reality, and politics) are implicated in any metaphysical characterization of the human. They are selected here because historically humans have depended upon the normative force of metaphysical ideas to regulate these realms in particular. Untold and innumerable injustices were perpetrated in these realms in the name of premodern metaphysics. Modernity sought to rectify these by turning to science alone, yet as the centuries unfolded the vacuum created by the *absence* of metaphysics continued to expand, and today *the absence of metaphysics is creating new and more dangerous problems*.

As a new metaphysics, cosmo-erotic humanism helps to explain a lot about human behavior, both healthy and pathological. This explanatory power shows that a metaphysics of Eros can be a reasonable extension of investigations in psychotherapeutic and developmental branches of psychology. Cosmo-erotic humanism also provides grounds for a critique of existing social conditions, especially in those realms where humans place tremendous value and emotional energy (i.e., in sexual relationships and in politics). The normative power of these critiques shows that a metaphysics of Eros can be a reasonable alternative to the absence of modern and postmodern metaphysics, which has now become a support for certain structures of love and politics that are systematically distorted. This brings us to the perennial metaphysical question of how a basic force of good such as Eros can ever become systemically distorted, and then through this distortion morph into Thanatos. Yet in order for this to make sense, it is necessary to explain why metaphysics is a sensible thing to talk about in the first place.

Part One
Practicing Metaphysics in a Time Between Worlds

> If before encountering otherness we already know what its relation to us will be, we have obliterated it in advance…. Kant still wants to say something about radical alterity, even if it is only that it has no relevance to us, yet he has deprived himself of the right to all speculation about the nature of what is beyond appearance…. [This]... delimitation of alterity... sets up the modern form of the ontological question: 'how do we know that matter exists?' That the very existence of materiality is problematic for enlightenment thought is symptomatic of the colonial trading systems that correspond to it. Alterity cannot be registered, unless it can be inscribed within the system, according to the interconnected axes of exchange value (price)… in other words, as a commodity….
>
> – Nick Land, (1988/2011) "Kant, Capital, and The Prohibition of Incest" (p. 64; 71).

The controversial philosopher, Nick Land, is often associated with the new schools of post-Kantian metaphysics known as *speculative realism* and *object-oriented ontology*. His political philosophy of "Accelerationism" and his writings on the "Dark Enlightenment" have been widely influential and tied into the resurgence of anti-postmodernist right-wing radicalism, as exemplified by the "alt-right" in the United States. I will explore Land's ideas further below; he is quoted at length to begin this section because his thinking and its impact are signs of the metamodern "return" to metaphysics currently demanded by the exhaustion of postmodernism and related major transformations in economic conditions. Right-wing and authoritarian political thought is resurgent today because of the *absence* of reasonable discourse about metaphysical realities during a time when exactly these realties are being called into question due to the apocalypse of global capitalism and the accompanying planetary transition into the *Anthropocene* (Stein & Gafni, 2015). As I discuss in the sections to come, our current decent into a dysfunctional "post-truth" and "post-love" culture is a case in point. Metaphysics has come home to roost in a supposedly "post-metaphysical" modern democracy. We now have TV news anchors and celebrity personalities who have never read a philosophy book discussing the nature of "truth" and "facts" on Saturday morning programs. The question of what is "real" and what is "fake" may have never been more confused in public discourse. The vacuum created by the feeling of "what is real?" will be filled in one way or another; as I explain below, metaphysics is unavoidable.

I have argued elsewhere (Stein, in press) that the social forms that come after capitalism and after modernity (the social forms that will be globally "sustainable") *may or may not* be more fair and humane then what we have known during the reign of the capitalist world system (e.g., since the long sixteenth century). What comes next will depend on our metaphysical characterizations of the human and the universe. The way we answer questions such as, “What is the human?” will determine the next century due to the emerging power of new technologies that render the human malleable in unpresented ways, which has been made clear by writers such as Yuval Noah Harari (2017). Metaphysics is necessary because we are in a time between worlds.

Metaphysics is a difficult word to define outside its simple origin as the title marking the volume that followed the *Physics* in Aristotle’s canon (in Greek, *meta = after / beyond*). In the West, metaphysics has been a distinct branch of academic philosophy ever since Aristotle’s works were translated by the Church. *Ontology* is a related word (based on the Greek, *ontos = being),* which I use to refer to the practice of working out the details within a larger metaphysical system. Medieval monastics would conceive some of the most complex and ornate metaphysical systems in history, justifying all kinds of miracles and biblical paradoxes through metaphysical theorizing and ontological speculations – and they would buttress it all with a theory of Intuition.

Premodern metaphysics is often what people think of when they think of metaphysics pejoratively as a kind of magical thinking (e.g., “how many angels can dance on the head of a pin?”). Premodern metaphysics also gets a bad reputation from having been used to justify the Inquisition, religious wars, and all manner of theocratic insanity. This is all true, but I am not out to beat the dead horse of premodern metaphysics, which both scientistic New Atheists and postmodern progressives continue to enjoy doing. Instead I am going to argue that contemporary cultural trends signal a “return” to metaphysics. I argue that the modern and postmodern *absence* of metaphysics causes its own problems, like those now encountered by the modern capitalist world-system as it reaches its terminal limits to growth. Part of responding to our global crises requires finding a way to live again within a metaphysics that puts the human being in context. The phrase “metaphysics after Kant” is used to talk about the difficulty that professional philosophers have in practicing metaphysics during our current epoch of cultural evolution.

Metaphysics was taken away from the religious authorities by Immanuel Kant during the Enlightenment. At the time, Kant was considered by some to be the most dangerous and revolutionary man on the European continent – more dangerous even than Napoleon. This idea was comical to others because Kant lived on a meager salary in the same small *attic* most of his adult life. He never traveled, supposedly never lost his virginity, supposedly never raised his voice in anger, and every day he took a walk at *exactly* the same time with such regularity that his neighbors set their watches by it (Cassirer, 1981). However, the quip about Kant being dangerous is funny because it is true. Kant’s project was radical (and more dangerous than violent uprisings) to the foundations of religious authority, and in turn to political authority. Kant had thought out a way to overthrow the *ancien régime* of Leibnizian “metaphysics as apologetics,” and in so doing to make separate places for science and faith under one system. Along with other thinkers of his time, Kant would literally destroy the way a whole culture justified its most important beliefs and values.

After Kant, metaphysics was done in a different way. Reality – the *thing-in-itself* – was put out of reach, which meant that theologians could no longer claim to have intuitions into divine ideas but also that science could claim only to “understand” and never to have the total truth. Science and theological metaphysics were put in their respective places by Kant’s “Copernican Turn” away from the objects of science and theology and towards the knowing subject. His so-called "transcendental subject" was what he thought philosophers should be researching instead of metaphysics, as it is prior to metaphysics. The categories of the subject that structure perception were more important for Kant than the "object" they perceived; he theorized that consciousness constructed the object and the whole of nature, including time and causality. Nature as it really is cannot be known. We can only know nature as it appears to us through the structures of our consciousness. Premodern metaphysics was over, and Kant had ushered in a new era in philosophy during which it would support the activities of the physical sciences while also being freed from the reigns of the church. As modernity progressed metaphysics would be denied and avoided, eventually withering away into the bare bones "flatland" universe implied by the physical sciences (see Bhaskar, 1986).

The practice of metaphysics was in disarray 78 years after Kant, when Darwin brought about the most massive changes to our understanding of the physical universe since Newton. Evolutionary theory would change what it meant to practice philosophy, and philosophers would slowly begin their journey "back" to metaphysics. Peirce was one of the first to follow the implications of evolutionary theory up into the aperspectival complexity on the other side of modernity (what we call postmodernism) and then beyond that into a new metaphysics of humanity and the universe (Brent, 1998). I have documented elsewhere Peirce's work as a proto-Integral metatheorist (Stein, 2015). Here I trace the development of his thought again (but from a different angle) in order to frame a discussion of what it means to do metaphysics after Kant and Darwin. I then follow a line through Peirce's semiotics and objective idealism to current trends in metamodern metaphysics, including speculative realism. Granted, there are other ways to frame a discussion of post-metaphysical philosophy besides my story about Peirce. For example, there is a line that runs from Kant through Heidegger to Badiou, and another from Hegel through Marx to Bhaskar (as it is, I arrive at Bhaskar via another route). I frame my account using Peirce because at the core of Peirce's scientific, post-Kantain metaphysics was the idea of *evolutionary love*, which is an important forerunner to the conception of Eros that is at the core of cosmo-erotic humanism.

Charles Sanders Peirce: Metaphysics after Darwin

Peirce memorized large sections of *The Critique of Pure Reason* when he was thirteen years old and then began his career as a scientist, a nominalist, and a materialist opposed to metaphysics. He would end his career as a polymath, a realist, an objective idealist, and deeply engaged in a new form of philosophy that he called "scientific metaphysics." Peirce's early work was focused on the scientific method and especially on producing a convincing theory of inquiry that took evolution into account (Peirce, 1867). This work has been well summarized by Elizabeth Cook (2006), among others (Apel, 1995). At issue was the status of the human brain and perceptual system, which could no longer be reasonably conceived as structured by God-given categories of experience, nor equipped with "divine intuition." Peirce argued that humans could never truly *know* the world once and for all, we could only endlessly learn about it by finding new ways to test our ideas through discourse and experimentation. He rejected the very idea of the abstract knowing subject of modern epistemology and replaced it with ideas about the *construction* of scientific knowledge by groups of people. Peirce was one of the first theorists of science to use the phrase "community of inquiry" and to engage in philosophy about the *practice* of science. In his pathbreaking explorations of the implications of modern science and evolutionary theory in particular, Peirce would come to see that the knowing subject is *within* the world, not outside the world looking in like Kant's "transcendental subject." Scientists are imbedded in the world as animals that evolved within the nature, and must arrange and interact with nature in specific ways in order to learn. Learning requires not perception and reflection but action and construction. Kant's transcendental subject was brought down to Earth and into process, social life, and organic form. By thus detranscendentalizing the subject, Peirce would take the first steps "back" to metaphysics (Habermas, 1992).

The idea of *detranscendentalizing the subject* is important but can be misunderstood. Peirce not only put the abstract Kantian subject into social and linguistic context (Hegel had already done that), he also put the subject into an evolved organism that itself was a potential focus of scientific inquiry. The knower (the one who knows, i.e., the subject) is a contingent part of nature and thus also open to scientific research and eventual disenchantment. Kant limited scientific knowledge about the nature of humans themselves to an afterthought in his *Anthropology*; his knowledge was not as advanced as the scientific psychology that Peirce was practicing in the 1870s. Many scholars forget that Peirce was arguably the first experimental psychologist on the North American continent (Brent, 1998). More than anyone up to that point in history, Peirce was directly fixing his scientific gaze upon the scientists themselves, studying various aspects of scientific judgment. What he discovered began to undercut his beliefs in both materialism and nominalism. Peirce would begin to do metaphysics again, in a new way.

In the 1890s, Peirce began a series of metaphysical investigations that ended up having a major impact on the future of philosophy. Alfred North Whitehead would later take directly from Peirce's metaphysics in laying the groundwork for his *Process and Reality*. Whitehead's process philosophy is another major metaphysical system that emerged after Kant and Darwin, which also places *love* near the ontological center of the evolving cosmos. Karl Popper (1966) would credit Peirce with ushering in a new era of thinking about complexity, chaos, and process – all facets of metamodern metaphysics (as detailed above from Freinacht, 2017 pp. 361-366). Habermas and Karl-Otto Apel would see in Peirce the possibility of a post-metaphysical philosophy, including a form of evolutionary realism that allowed for a speculative scientific metaphysics of evolution (Apel, 1994; 1995). Ken Wilber saw in Peirce a theory of *cosmic habits* and pansemiosis, while Gafni and Stein found his notion of evolutionary love prophetic (Gafni, 2012a; Stein, 2015).

It is worth mentioning that by this point in his life Peirce was exiled from the academy; this in part explains his continued obscurity. Peirce was subject to an organized smear campaign involving the core of American academia, which was at the time a small and insular place awash in contradictory Victorian-era ethics (see Brent, 1998). Peirce's divorce and remarriage were all that competing mathematicians and philosophers needed to reframe some of Peirce's personality traits as deeply unethical character flaws. Before long he could not find a job and was stuck writing definitions for James Mark Baldwin's *Dictionary of Philosophy and Psychology*. Baldwin had also been kicked out of American academia due to a politized smear campaign (I discuss Baldwin further in Stein, 2015). Were it not for the generosity of his dear friend William James, Peirce would never have completed any of his metaphysical work during this time. The mischaracterizations of Peirce that began in the 1880s have been repeated up to this day, as can be seen in the popular book *The Metaphysical Club* (Menand, 2001), that presents an intellectual history of the American Pragmatists that downplays Peirce's catalytic role in the movement (while also defaming his character). Peirce's treatment makes some sense in the context of understanding the "the murder of Eros," discussed at some length below.

Living in poverty and obscurity in 1903, Peirce defined metaphysics as a branch of phenomenology (or what he called *phaneroscopy*: "the study of common experience"). This practice was wedded to the special sciences (i.e., physics, biology, psychology, etc.) and was a condition for the possibility of their success. "Its [metaphysics] business is to study the most general features of reality and real objects" (Peirce, 1934 p. 5). He maintained that the immature state of metaphysics was hindering the sciences and aimed explicitly to do his metaphysics in the service of future science. Peirce (1934) argued that metaphysics was too often dismissed due to the belief that it is unscientific because it deals with things that cannot been seen or tested. Yet this is not true:

> The things that any science discovers are beyond the reach of direct observation. We cannot see energy, nor the attraction of gravitation, nor the flying molecules of gases, nor the luminiferous ether [ZS: this ether was a postulated medium for the propagation of light in the nineteenth century], nor the forests of the carbonaceous era, nor the explosions in nerve-cells. It is only the premisses [*sic*] of science, not its conclusions, which are directly observed. But metaphysics, even bad metaphysics, really rests on observations, whether consciously or not; and the only reason that this is not universally recognized is that it rests upon kinds of phenomena with which every man's experience is so saturated that he usually pays no particular attention to them. The data of metaphysics are not less open to observation, but immeasurably more so, than the data, say, of the very highly developed science of astronomy, [where] to make any important addition... [costs] many tens of thousands of dollars [ZS: tens of thousands of dollars in 1890; today it's tens of billions of dollars]. (p. 2)

The fact that the Peirce quote above contains an outdated scientific concept is exactly the point. Scientific *practices* precede and outlive scientific *concepts*. The truths of science are not as readily available as some would think (they also tend to come and go) and they are not more readily available than the truths of metaphysics. The difference between metaphysics and science is not about what you can see and what you cannot see; it is about what you are paying attention to when you are seeing. Humans are seeing reality all the time, they just have to recognize it and figure out how to learn from what is real.

What Peirce (1933; 1934) called *phaneroscopy* would today be viewed as a form of scientific phenomenology (note that both words are from the same Greek root *phainómenon*, meaning roughly: "thing appearing to view"). The closet contemporary approach to Peirce's version of phenomenology would be the *enactive paradigm* of Francisco Varela, Eleanor Rosch, and Evan Thompson (1991), who meld Buddhist meditation with cognitive science to yield a new way of thinking about organisms as knowers. This so-called "Santiago School of Cognition" since has already been identified by William Irwin Thompson as containing the seeds of a new metaphysical characterization of the human (Thompson, 1998). But Varela, Rosch, and the Thompsons take things in a different direction than Peirce, who considered phaneroscopy the most foundational branch of philosophy, essential for doing science, but not itself a science (strictly speaking).

Peirce (1934) understood that you cannot use science alone to investigate and justify science. Instead you need to do metaphysics (i.e., you need to investigate the very possibility of truth), and the data for this is to be found in the *common experience* of the human organism. Peirce was investigating common experience, but not in the sense of experiences that are frequently had by large numbers of people. Rather the experience is “common” because it is universally available as an aspect of being human. One could argue that Buddhist meditators are investigating common experience in this way. Experienced meditators become aware of things that most people are not aware of, which are nevertheless there all of the time. Peirce was seeking to investigate questions such as: What are the most general features that the universe must have for my experience to exist? And by implication, what must the relationship between the world and mind be like for scientific practices to work? The most basic practice of metaphysics begins with the most basic elements of human experience itself. Peirce would engage in these kinds of investigations in the midst of doing science across nearly a dozen fields. He would also investigate the common experience found in the practices of mathematics and logic and explore the metaphysical implications entailed by the success of mathematics as a human practice (i.e., why is it that our mathematical constructs relate to the world with a great deal of consistency?).

Using this method, Peirce (1933; 1934) was able to discover and justify his system of metaphysical categories, which he called “Firstness, Secondness, and Thirdness.” Peirce’s early articulations of these categories would inspire Habermas and Wilber to map their own systems of categories in terms of the basic parts of speech found in all languages – I, We, and It – thus marking out three “worlds.” Peircean categories are different from Kantian categories because they are not only properties of the subject*;* Peircean categories transcend and include both subject and object, co-arising as basic properties of all reality. Peirce placed the Kantian subject firmly in the Darwinian universe and thus did not see consciousness as separate from nature. Kant declared to have found in consciousness a “world constituting power,” declaring that consciousness constructs nature and is thus not a part of nature (and so followed much of modern thought). Peirce said that such a view is only one third of the story. Yes, consciousness constructs nature, yet nature has constructed consciousness over the course of evolutionary timescales that would make Kant dizzy. Moreover, Peirce believed that once consciousness has emerged from nature, it then acts back upon nature and itself to initiate an auto-evolutionary process that unfolds *evolutionary love* at higher and higher levels of complexity. The dialectic between subject and object is an erotic merger that yields emergence, novelty, and meaning. But this is getting ahead of the story. The point here is that Peirce’s categories are post-Kantian and clear the way for doing metaphysics again.

For context, I will add that a handful of contemporary thinkers follow Peirce in arriving at ontological categories through what has come to be called the “rational reconstruction” of common experience. Ken Wilber’s (2006) post-metaphysical justification of the quadrants and 20 tenets, as well as his integral methodological pluralism, have been derived via methods similar to Peirce. Wilber asks: What are the ontological conditions for the possibility of an integration of all existing methods for creating knowledge? (Another way to ask this is: What must the universe be like for all the various branches of valid knowledge to be true?) Habermas (1998) argues for ontologizing the three “worlds” that he derived through the rational reconstruction of the common experience of communication. Habermas asks: What are the ontological conditions for the possibility of communication? (Or: What must the universe be like for human mutual understanding to be real?) Bhaskar’s (1986; 1998) critical realism hinges on an updated version of Kant’s transcendental argumentative strategies. Bhaskar asks: What are the ontological conditions for the possibility of scientific practice? (Or: What must the universe be like for science itself to be a successful practice?) Finally, to foreshadow my discussion of the book *A Return to Eros* (Gafni & Kincaid, 2017), I will mention that Gafni and Kincaid ask: What are the ontological conditions for the possibility of human love? (Or: What must the universe be like for human love to be real?) All of these approaches to practicing metaphysics after Kant and Darwin share a common method of deriving insights into the basic structures of reality itself through a careful investigation of (and extrapolation from) specific universal features of human experience.

Peirce repeatedly stresses the *necessity* of extrapolating from what is given in experience in order to discover what is real. *A Guess at the Riddle* is the title of the cryptic text at the core of Peirce's metaphysical system. The manuscript remained unpublished, even in the initial *Collected Papers of Charles Sanders Peirce*, and yet it was almost certainly in Whitehead's desk drawer for years (Brent, 1998). The initial *Collected Papers* were edited by Whitehead's best doctoral student at the time, Charles Hartshorne, who would himself go on to build a complex *process theology* based on Whitehead, Peirce, and others. For Peirce, *A Guess at the Riddle* began a decades-long inquiry into the ontological nature of evolution as it unfolds through the three categories. *Speculations* about what is real (i.e., *guessing*) is what scientists like to call "hypothesis generation." This is the source of everything we know "beyond" what is simply given in our experience. Peirce developed a whole branch of logic dedicated to hypothesis generation (Cook, 2006). He believed that while empirical methods are essential to science, the creative imagination of the scientist is the ultimate catalyst in the progress of knowledge about reality. The scientist is by definition doing a kind of metaphysics in these *necessary* moments of speculation that occur during their scientific practice.

Unlike the scientist, the metaphysician resides in the liminal space of speculation and seeks to accumulate and integrate all the speculations at the edges of all the various branches of science. A scientific metaphysics proceeds in advance of all the specific sciences, transcending but including them (while at the same time justifying them). Metaphysical speculations ought not contradict what is given by the best sciences of the day, but as metaphysical ideas they are also not to be limited by these sciences. Peirce saw that the theory of evolution and a host of other theories in biology were pointing towards an underlying and self-organizing force at work in evolution; he saw that among the tendencies and forces of nature is a force that unites, synthesizes, and creates higher-order communion among parts. Peirce's theory of *evolutionary love* is a speculative guess at the riddle presented by the sciences of his day. For Peirce, a metaphysics of Eros held the possibility of reconciling the lived experience of humanity with the revelations of science.

Many things have happened since Peirce first began the practice of doing metaphysics after Kant and Darwin. Arguably the most important and novel emergent since the Gilded Age has been the advent of the Internet. It should be noted in this context that Peirce followed Leibniz in speculating that the very structure of mathematics and logic includes the possibility of building a "logical machine" (Peirce, 1887). Peirce was aided in his work by one of his most talented doctoral students, Christine "Kitty" Ladd-Franklin, who was the first women to get a PhD in mathematics and logic. She was also a psychologist and was inspired by Peirce's ideas about mathematics and the possibility of building a machine that could think. In her conversations with Peirce (of which there is no record) one imagines that the foundations of logics and mathematics were ontologized *beyond* the human organism, and thus beyond the ontology of gender itself. In my imagination this makes Ladd-Franklin the first cyberfeminist. Cyberfeminism is a topic I explore below as part of the metamodern return to metaphysics. Regardless of what Franklin-Ladd thought when she and Peirce explored these ideas together at Johns Hopkins, the time would soon come when computer technologies would begin to change what it means to be a human. Soon, Sadie Plant and Nick Land would become some of the first to begin to do metaphysics in and about cyberspace.

Sadie Plant, Nick Land, and the Cybernetic Cultural Research Unit: Guerrilla Ontology

Metaphysics has become an even more complex practice today following the explosion of unprecedented interconnectivities between people based on new communication technologies. The historical co-emergence of popular (pop-)postmodernism and computer technologies is not a coincidence; modernity's tendencies towards subjectivity and abstraction were sent into overdrive by the proliferation of communication technologies, something I explore in detail later in this paper. It is as if the problems posed by Kant's transcendental subject were deepened to the point of being entirely transformed. Kant's point that *consciousness creates reality* has been driven home by a new fragmentation of subjectivities in which individuals became increasingly engrossed in their own private virtual worlds, seemingly out of touch with each other's realities. More importantly, computers also have made it impossible to deny that consciousness itself is created through the conditions of material reality. Silicon is now part of the evolution of consciousness. Our minds and the categories in terms of which we understand the world are now being *extended* by computing power. The near exponential growth of computer technologies has made all too apparent the *materiality* that is a condition for the possibility of the evolution of consciousness. It is important to understand that today our minds depend upon matter in new and unprecedented ways. Our thoughts and memories are now enmeshed in complex configurations of silicon and other materials that are beyond the limits of our nervous system and skin, at least for now (*cyborgization* is a topic beyond the scope of this paper).

I am extending here the idea of the *extended mind*, which emerged in cognitive science and philosophy around the turn of century (Clark & Chalmers, 1998). Computer technologies made clear a basic truth: the human mind has *always* been extended out into the environment. From cave paintings to calendars made of stone, we build scaffolds around the self that become part of our cognitive being. Interestingly, timekeeping in particular *requires* externalizing subjective time into objective time through the utilization of complex material objects that encode time. We use matter to make the reality of the passage of time available to cognition, action, and self-understating. At first this was done through the observation of the stars and then through the construction of complex architectural arrangements built to track them. Sundials and water clocks predate ancient history. Clocks as we know them are a relatively recent invention; a watch that anyone can wear is even more novel and recent.

It is worth thinking about this example because time keeping is something unique that sets humans apart in the animal kingdom. While animals are clearly aware of time, they do not, for example, know how old they are. Animals know something like "spring is coming" (absent of propositionally differentiated speech, of course), but animals know nothing like, "this is my 38th spring." The animal's mind is also extended into its environment, but not reflectively or technologically. I am not trying to draw a stark line between humans and animals (because there isn't one), but I am suggesting that the human mind has evolved in part through its ability to use the world and its material affordances to aid human understanding itself. The minds of all animals are extended into their environments in many ways, a point made by the Santiago School of Cognition's enactive paradigm. But only the human mind reflects upon its own extensions into the world, which allows us to use the environment for cognitive purposes. Our mind's abilities are not only a matter of what is contained within our skin, which is an important insight to remember when we begin to discuss the metaphysics of Eros entailed by cosmo-erotic humanism. For example, the smartphone enables a new form of subjectivity (for better and for worse), and new conditions for the evolution of love and relationship are now available. Specifically, smartphones change our experience of the reality of time, space, and identity, which is to say they have metaphysical implications.

This last statement about the smartphone is inspired by what Sadie Plant has been arguing. Plant is a catalyst for cyberfeminist writings and was the alleged co-writer of a pseudonymous collection of "theory-fiction" fragments attributed to the Cybernetic Culture Research Unit (2017). These texts were part of the birth of *speculative realism*. Nick Land (2011) was also a midwife to speculative realism as well as an alleged co-creator of the Ccru (sic). For the Ccru, taking the impact of computers on consciousness as seriously as possible means returning to metaphysics – returning to a form of metaphysical *realism* specifically. Remember that Kant was an idealist – he believed that the mind creates reality. For idealists (and most *nominalists*), matter is less primordial than the mind's categories. Realists, on the other hand, maintain that that a structured reality exists beyond the human mind and that material reality includes emergent structures and processes that transcend and include the human mind. The human mind can therefore know reality (to some extent) through participation in it and as it.

Realism is entailed by computational extensions of human consciousness because ultimately *code itself* becomes identified as undeniably real, structured, and outside the mind. Just as Darwin forced Peirce to put the transcendental subject into a nervous system and into the natural history of an evolving planet, so computers forced a further pulling of the mind "down" into matter. In philosophy this marked a deepening of the "return to the object" (i.e., a return to considering the world beyond the mind as knowable, structured, and real). These trends "after Kant" put humans back in their place, not as a floating transcendental subject, but as embodied (and encoded) in space and time. Nick Land speculates (along with others) that time itself is best explained in terms of a metaphysics that posits each person's total immersion in a computerized world-simulation (like in the movie *The Matrix).* With these speculations Land is seeking a transcendence of modern and postmodern forms of human subjectivity and is willing to take on a complex transpersonal metaphysics to do so. While I think his speculations are deeply confused, I also think they are a sign that basic metaphysical issues are once again being forced onto the table, even if it is just in the movies.

The Ccru uses science fiction as an entryway into metamodern metaphysics, finding a new location for the creation of speculative ontologies extrapolating from scientific advance. The Ccru is practicing a kind of "guerrilla ontology" by using the text itself as a means to alter consciousness and awareness in the moment for the reader. *Guerilla ontology* is a term used by the early metamodernist Robert Anton Wilson to describe his own work (Wilson, 1977/2016). The term suggests that the practice of metaphysics today can involve stepping outside of the centralized command and control structure of academic philosophy and engaging in all kinds of covert tactics, including theory fiction, anonymity, and revelations of the truths found in first-person experience. The guerilla ontologist forces readers to confront new realities in their own first-person experience by inviting (or jarring) them into uncanny phenomenological experiences. This is a common tactic among metamodern metaphysicians who are seeking to alter the consciousness of their readers in real time as part of justifying ontological arguments.

Following postmodernism's critiques of abstract theorizing, it makes sense that metaphysics has taken a "participatory turn" (Ferrer & Sherman, 2009). Practicing metaphysics now demands more than reading and writing theory in the traditional academic sense. Doing metaphysics means engaging in behaviors traditionally understood as "rituals," as well as in specific practices that allow individuals to see their own experiences objectively. Below I explore how Gafni and Kincaid practice guerrilla ontology in their explorations of human sexuality and love, revealing uncanny mystical experiences in the songs and films of popular culture. As we are exposed to different and larger realities already within our own experience, we are also invited to change our life and the world. The implication of all forms of participatory metaphysics are ultimately political.

It makes sense then that Nick Land's writings on politics have gained as much attention as his metaphysical speculations. Land has been promoting a certain kind of *Accelerationism* that seeks the political means to hasten the coming of the techno-capitalist singularity, and thus to catapult Earth into a transhuman future. Land is driven to these extremes by his ontological considerations about the new realities of planetary-scale computation. The phrase "planetary-scale computation" has been made popular by Benjamin H. Bratton (2015), who has theorized about our historical moment as involving the creation of an Earth-sized computer, which he calls "The Stack." The basic question is: At what point does this planetary computational stack replace reality? At what point in history does code itself become more real and world-creating than even the human subjectivity that writes it? Land's techno-*Logos*-mysticism presents a world in which humans are not in control of their future because laws of computation and "machinic desire" have already transcend but included them (Land, 2011 p. 319); we are being swept along by these laws into realms of human obsolescence that are politically unprecedented. Land's speculative realism eventually turns towards forms of political thought that have long been discredited by modernity and postmodernity. Neoreactionary forms of fascism have been inspired by Land's work because of his unabashed embrace of realities that contextualize human subjectivity and desire in broader geo-historical and ontological dynamics. The metamodern return to metaphysics also marks a return to metaphysically inspired political ideologies as well as their accompanying emotion and violence. The vacuum created by the modern and postmodern absence of metaphysics is now being filled, for better or worse. Land's work is one attempt to fill this void of meaning – it signals the dark possibilities entailed by the metamodern return to metaphysics.

Cosmo-erotic humanism is another attempt to fill the void of meaning left by postmodernism. Cosmo-erotic humanism is a project of reconstructive metaphysics and metatheory that is aimed at fostering cultural evolution at planetary scale, not towards some techno-capitalist singularity, but towards a planetary awakening of humanity through the propagation of innumerable "Unique Self Symphonies." However, unique individuals can only freely join into symbiosis and community in light of shared narratives of *identity, universe, and power* – some kind of metamodern metaphysics is a prerequisite for planetary cultural coherence and the future of geo-politics (Stein & Gafni, 2015). This is an attempt to embark somewhat in advance of humanity's inevitable and immanent journey in metamodern metaphysics. I now turn to discuss Gafni and Kincaid's (2017) work as a way of looking into what it would mean to adopt the metaphysics of Eros at the core of cosmo-erotic humanism.

Part Two
Exploring a Metamodern Metaphysics of Eros

At the heart of *A Return to Eros* (Gafni & Kincaid, 2017) is a new metaphysical narrative about love and sex. The book seeks to salvage the reality of love in a time when love is being trivialized and forgotten. It argues that love is not merely a human construct. What humans experience as love and sexual desire are but facets of Eros, a construct nearly identical with Peirce's *evolutionary love* – the force that drives reality itself towards greater contact and larger wholes. *A Return to Eros* offers a metaphysically grounded Tantric praxis that is refreshingly different from the contemporary Western neo-Tantras that focus almost exclusively in the realm of sexual techniques. Like the original Tantric schools of thought in Kashmir Shaivism, *A Return to Eros* focuses on the fundamental frameworks of reality that shape human narratives of identity, power, and community which must be derived from a larger Universe Story – a new metaphysics. Only in the light of this broadest context can a coherent narrative about love and sex be read. Thus, Marc Gafni and Kristina Kincaid are not writing about sex and love; they are writing about Eros, which is ontologically prior to sex and love. There was a billion years of Eros before sex. Eros is built into the dynamics of reality itself. The love life of humanity is but an expression of *evolutionary love*, which pulses through all forms of life.

While this idea reminds us of Peirce's essay, Gafni and Kincaid would make Peirce blush as they unpack the obvious implications of his train of thought. Indeed, many evolutionary theorists fall short of the full implications of what it means to hold an evolutionary worldview. Engaging in a participatory metaphysics of Eros involves a realization that evolution is *not* a process happening "out there," merely to be studied from the third-person point of view. Our lives and relationships are the very stuff of evolution. The "self-organizing universe" continues on through us; the core of human interiors and consciousness are nothing but our inheritance of a cosmic *evolutionary love*. This must be the basis of any science or psychology of human behavior and motivation. Reality itself has been shown to be ceaselessly creative and driven always by an erotic advance into novelty, which means that ethics needs to be appropriately reconstructed.

This is the kind of reconstructive metaphysical project that *A Return to Eros* begins to attempt. Gafni and colleagues at the Center for Integral Wisdom (among whom the author of this review counts himself) are gradually evolving an approach to the reconstruction and evolution of culture on a planetary scale. *Cosmo-Erotic Humanism* is how we describe the emergent worldview taking shape. *A Return to Eros* offers an essential element in this worldview, developing the themes of Eros and identity already articulated in Gafni's mainstream and highly popular releases *Soul Prints* (2001) and *The Mystery of Love* (2003). These were followed by Gafni's major academic work, the two volumes of *Radical Kabbalah* (Gafni, 2012), which I have reviewed elsewhere (Stein, 2014). A genre-bending form of mystical hermeneutics, ecstatic scholarship, and participatory metaphysics lie at the core of Gafni's writings and informs all of his thought. *Radical Kabbalah* was to be the source of Unique Self Theory (Gafni 2012a; 2015), which offers new and powerful frameworks for approaching issues in transpersonal psychology, human development, and identity theory.

Gafni himself has been subject to an ongoing political smear campaign proven to involve power and deception within rabbinical and New Age circles in Israel and the United States (Fuhs, 2017). The content of Gafni's teachings and the attacks against him are related. The embattled context of Gafni's scholarship can be felt in *A Return to Eros*, which is co-authored with Dr. Kristina Kincaid, who has a background in the application of Wilhelm Reich's core energetic therapeutics. In some sense, *A Return to Eros* is a response to the forces in culture that allow for smear campaigns involving the weaponizing of personal stories about sex, so often hidden under the fig leaf of victim advocacy. The book is also a powerful response to the forces in culture that perpetrate sexual violence and perpetuate the legacies of patriarchy and sexism. My particular goal here is use *A Return to Eros* as a way into the possibilities of the broader program of cosmo-erotic humanism. I place Gafni and Kincaids's book squarely in the center of our current cultural upheavals. As the force of reason in the public sphere weakens, the roles of innovative intellectuals, teachers, and writers become precarious. Gafni and Kincaid are working at the nexus of sex, reality, and politics, which is one of the most dangerous places for anyone to undertake innovation.

Sex, Reality, and Politics: Thinking Dangerously

Some years back, Slavoj Žižek, a newly popular Slovenian Neo-Marxist Philosopher and Psychoanalyst, was nicknamed "the most dangerous philosopher in the West," in what appeared to be a stunt arranged by his publicist (Oehmke, 2010). However, the idea of Žižek being dangerous seemed feasible because he was writing at the interface of sexual desire, philosophy (specifically ontology), and politics. This combination is dangerous in many cultural enclaves, even if Žižek is too abstract and obfuscating to really be a threat. Sexuality and desire are the keys to the domains of shadow; the *erotic* is thus taboo in cultures that are shadow-avoidant. Ontology is about what is real, what exists, and what is actually the case. The truth (the *alethic)* can be as taboo as sex in cultures that are reality-avoidant. Politics is about the *ethos* that governs human behavior and cooperation and is often avoided when cultures are unclear about what is in the interest of the common good. Putting all three topics into one book is usually a recipe for something provocative and potentially even dangerous to a wide swath of cultural and scholarly positions. Žižek ultimately argues for critiquing the political-economy of pleasure and related ideologies of (anti-)enjoyment. Conventional norms of behavior, consumption, and entertainment are cast in a critical light and explained as distortions of erotic energy – perversions of the ontological reality of desire itself. In other words, desire can be directed away from what truly satisfies it and forced into channels that exploit and distort our most basic human energies. Žižek the Christian says that what people really desire is love; to drop all their distractions and find the Real that is Love – a radical and "dangerous" sentiment.

Gafni's and Kincaid's book is also "dangerous" in this way, but make no mistake: *A Return to Eros* (Gafni & Kincaid, 2017) is as far from Žižek as you can get in terms of style and content. Where Žižek reads like a hyperactive neo-Hegelian movie critic, Gafni and Kincaid read like slightly buzzed Rumi scholars sharing Passover. *A Return to Eros* is dangerous because it brings together that same set of dangerous themes (sex, reality, and politics), and brings them down to

Earth for the twenty-first century. These themes have been the focus of most dangerous thinking in the modern age, starting with Marx and Freud. Before that it was figures such as Christ and Buddha who told humanity what to make of their desires, reality, and society. Worldviews do many things, but they especially make sense of human desires and their relationship to truth, goodness, and community. As *A Return to Eros* teaches, if you can *clarify desire* and in so doing attune your desire with reality, you will not be trapped in the pseudo-desires that are multiplied by the political economy of enjoyment. This is why the nexus of sex, reality, and politics is the linchpin of culture. Today sex, reality, and politics are incoherent aspects of a post-truth culture where narrative trumps truth (Wilber, 2017). Cultural warfare is spilling from our screens into the boardroom, bedroom, and dining room as the domain of the political is expanding to encompass all that was once personal. Throughout the US people are taking to social media and to the streets in displays of emotion escalating towards violence.

To understand the arguments, frameworks, and practices in *A Return to Eros,* one must understand the major traditions from which it stems: Hebrew wisdom, the mystical traditions of Tantra, modern evolutionary science and systems theory, Reichian praxis, and integral theory. We move towards a path out of the contemporary culture's "emotional plagues" (Reich, 1953) and "mimetic violence" (Girard, 1989). Gafni and Kincaid make clear it that the problems that face us at our current historical juncture stem from profound distortions of Eros – distortions of the basic emotional energies of humanity. Yet there is a possible future in which humanity gains clarity about what is valuable and certainty about the reality of love.

Implicit within the participatory metaphysics of *A Return to Eros* is a framework for cultural diagnostics that is directly relevant to our current cultural "dis-ease." The book pulls together fragments of a new psycho-sexual-spiritual critical theory of self and society. I am writing within the framework of academic critical theory, metaphysics, and metatheory. But *A Return to Eros* is not written or intended to be received in this way; it is not a book of academic critical theory or a formal work of metaphysics. It is a book of inspired and poetic text intending to evolve the very source code of love itself with new possibilities and emergent worldviews. And while it is laced with academic references, it is not written to merely convince the reader, it is written to provoke and transform the reader. As guerrilla ontology targeting the core of emotional life, *A Return to Eros* is about the source codes of erotic emotional structures and how these relate to reality, and in turn to relationships, ethics, and the political. This potent combination of sex, reality, and politics makes for a dangerous book of metamodern metaphysics.

Emotion, Eros, and Evolution

The 1960s generation read dangerous books by Herbert Marcuse (1955) and Norman O. Brown (1959; 1966) and discussed the many ways that liberating our sexuality and rethinking our relationships would remake the face of society. Today in the context of resurgent patriarchy and fundamentalism, as well as the new puritanism of revived anti-sexuality rhetoric, the hopeful thinking of a generation dedicated to "free love" seems like a sentimental memory. As I later explore here (and as Gafni and Kincaid discuss), explanations exist for why cultures engage in shaming, scapegoating, and distorted displays of emotional energy. The misdirection of Eros leads to distortions of cognitive framing and political action (Bhaskar, 1993; Reich, 1969). *The structure of emotion is prior to the structure of thought*. Emotion is thus prior to (and a foundation for) the domains of the political and epistemological. This has been shown by neuroscience and educational research for decades (Apple, 2001; Damasio, 1994). It is one of the major claims implicit within *A Return to Eros*, where it is shown that errors in thought and ethics can be traced back to failures of relationship, failures of intimacy, and distortions of Eros.

Looking to Eros as the source code of human emotional structures means looking into the roots and dynamics of embodied "bio-psychic" emotional energy. Emotion is traced back to its root as the primary force of Eros that suffuses all reality. For Gafni and Kincaid, this is where metaphysics merges with the limits of psychological theorizing. They maintain that the psychological and biological sciences suggest that a principle expression of cosmic energy itself can be found in human sexuality. This is about the evolutionary significance of sex itself, which has been part of cultural common sense since Freud. As Gafni and Kincaid say repeatedly, "It is all about sex. And it is not about sex at all." Humanity's lifeline to cosmic evolution – where our personal energy plugs into the Universe – is through the sexual. But sex is not the source; rather, it points towards the source. There were billions of years of self-organizing and Eros well before sexual reproduction began.

Evolution was primarily *about* sex for millions of years; humanity is in the unique evolutionary position to ask what *sex itself* is about. The only way for humanity to evolve is to clarify the desire of the universe itself, which has been gifted to us, hidden in the secret of our sexual desire. Sexuality leads beyond sex and into Eros, which permeates all forms of creativity and flow-inducing mergers of self, object, and other. This is what Gafni and Kincaid mean when they write that sex is only a sign pointing towards Eros: the sexual models the erotic. *A Return to Eros* expresses one of the core teachings of Hebrew Tantra: that the desire of the universe itself is hidden within the nature of human desire. Human yearning – when it is clarified from the dross of grasping and illusion – is the yearning of evolutionary love itself, awakening in us. Gafni elucidated the great Kabbalistic mystic Luria in *Radical Kabbalah* by focusing on *the clarification of desire* as a mystical practice. Wisdom is seeking to align desire with reality. Our embodiments of Eros (our emotional structures, and by implication our personalities, thoughts, and actions) are not simply ours. As it reaches expression in and through human emotions, Eros is a force that transcends but includes the "skin-encapsulated ego;" humans participate in the erotic energies that constitute the evolving universe as a whole.

Western stereotypes would have us believe that Eros (as expressed in human emotion in general, but especially sexual attraction and love) drives us to error and should be avoided when trying to use reason. There is a moment of truth in this that has been well documented in research on cognitive bias (Gino, 2013). Indeed, it is clear that some forms of emotion can profoundly distort our ability to think clearly and make good decisions. However, a careful look at this research shows that it is not the lack or absence of emotion in general that is important for reason and clarity of decision-making, but rather the *presence* of certain positive emotions. Research on how the brain learns also shows that you need a kind of *passion* to learn, otherwise you forget or simply give up (Immordino-Yang, 2011). It is only when life is rich with emotion, when you are in the flow of Eros, only then are you ever really thinking clearly. Ask a world-class scientist what it is like to really be *doing* science, and they will describe a kind of rapture, using words like beauty, ecstasy, and satisfaction (erotic emotional highs often following from rigorous preparation; no doubt, foreplay is important). The underappreciated implication of this is *not* that we should repress emotion and get it out of the way, but rather that if we want to be reasonable we should work hard to *cultivate* and *clarify* certain emotions.

The clarification of emotion has long been part of the great Tantric traditions of spiritual practice. *A Return to Eros* demonstrates that the goal of Tantra, so often misunderstood in popular narratives, is *not* more and better sex, but rather more erotic energy to be expanded beyond the sexual. As Gafni has been saying since he wrote *The Mystery of Love* (2003), "the sexual models the erotic, but it does not exhaust it." In sexual experiences the majority of people can most easily experience the various qualities of Eros. The emotional intensity of sexuality explodes the powder keg known as the system, plugging into billions of years of evolution. Tantra seeks to transform and liberate this energy – which is the basic bio-psychic energy of evolution itself – so that it transcends but includes the domain of sexuality. This is seen as the key to a liberated humanity: clarification of what is hidden in erotic merger, and then expanding this pure erotic energy into the rest of life. Literally a return or turning towards Eros, this is the wellspring from which the actualization of human potential flows.

The many qualities of Eros detailed by Gafni and Kincaid are listed as the "12 faces of Eros." Each one gets a chapter. Some of these faces are the qualities of flow and self-transcendence, peak experiences, and mystical merger, as were researched in the human potential movement for decades (Murphy, 1992; Wheal, 2017). Other qualities instead challenge the non-dual Eastern orientations of the human potential movement. Just to get a sense (although there is not space to discuss them here), the most essential of the 12 faces of Eros are: *interiority*, or depth of consciousness; *presence*, or the fullness of the moment; *desire*, or yearning; *wholeness*, or radical intimacy; and *uniqueness*. These are the results of Gafni and Kincaid's important work engaging a *phenomenology of Eros*, which amounts to a metamodern participatory metaphysics of the human understood as a function of cosmic Eros. Their work seeks to reveal the common deep structures of emotion that constitute the domain of the erotic. Is there a common structure to feelings of sexual merger and, for example, the feeling of being "at one with" a landscape that presents a rapturous sunset? Those two emotional structures are similar; both are rooted in Eros, and both are presenting a shade or face of Eros. Human love and sexuality is a *sign* that points beyond itself towards the Eros and Divinity of life itself. If we ask what the universe must be like for human love to be real, we ought not look only at the sign (you voyeur!), but to where it points.

All this echoes Reich (1969) and other theorists who critique the Left for abandoning the "sexual revolution" to those who want to debate gender politics (Thompson, 1981; 1998). The true sexual revolution would be a widespread liberation of Eros beyond the sexual, such that the energies of love, depth, and desire suffuse all aspects of life. This means that understanding the cultural crisis of today requires more than looking at developmental structures of thought and value, as Ken Wilber (2017) does in his analysis of *Trump and a Post-Truth World.* This developmental-structural approach is essential. But fully understanding and being able to take action requires looking further into the source code of emotional structures, and specifically recognizing the ubiquitous culture of what Gafni and Kincaid call *the murder of Eros*.

The Murder of Eros

That the root of human emotions is to be found in cosmic Eros explains, in part, the general sense among (especially conservative) psychologists and sociologists that humanity is sitting on a powder keg known as the system. The sense that human sexuality is an infinite energy that needs to be bottled up tight can be seen throughout the history of ideology. Reich (1953; 1969) spoke of the murder of Christ as a symbol for the perpetual and sometimes brutal domestication of Eros demanded by the ideologies of imperialistic capitalism. Reich was himself basically murdered by the FBI, which investigated and convicted him as a con man and sentenced him to prison, where he died only weeks later. They also burned his books, manuscripts and notes. Yes, this was after WWII when the FBI had a public book burning of Reich's books (Wilson, 1977/2016). Reich's status as a criminal has been reassessed, but the defamation of his character continues at the hands of traditional psychologists and conservative sexual counter-revolutionaries (see Reich's Wikipedia page, for example, where he is portrayed as an insane sexual deviant, an account that includes inaccuracies that his followers have been unable to amend, despite petitioning Wikipedia).

Reich argued that the structures and dynamics of emotional self-regulation demanded for participation in society have historically worked against the free and full range of emotional expression, especially in the domain of sexuality. The impact of this erotic truncation has been a distortion of the "upper-layers" of personality, thought, and action that depend upon this foundation of structured bio-psychic energy. Eros enlivens the body to the degree made possible by the structures of culture, society, and personality. Every society murders Eros in some specific way; the signs of this act can be found in the structure of embodied bio-psychic energies that constitutes the population. The murder of Eros shapes the character of a people. Culturally widespread distortions of personality, thought, and action can be understood not as some "mass or mob psychosis," but rather as a symptom of the countless individuals with emotional lives that share a similar distorted deep structure. The murder of Eros is always disguised. For example, limiting erotic energy to the merely sexual is a kind of erotic truncation, and perhaps the most common in our culture. An apparently liberated hook-up culture in which the mere act of sex is the most intimate thing shared between people distorts Eros in a different way than a traditional culture that would limit all sex to the marriage bed (with the lights off). But note that both truncate the erotic itself into the constraints of genital sexuality.

Of course, for large parts of the world, Eros can not even get out of the gate. Liberating traditional and fundamentalist religious cultures from overt forms of sexual repression is a global ethical imperative, and the only way to get billions of girls a proper education (Nussbaum, 2000; 2006). Patriarchy has long been at the core of our culture's domestication of Eros. Reich (1969) showed definitively the relationship of authoritarian patriarchal families and imperialistic industrialized capitalism, a combination of repression and pseudo-Eros that eventually culminated in fascism (see also Deleuze and Guattari, 1977/2009). Whole populations voted and acted against their own economic and political interests as if blind to the reality of their own situations, preferring instead to live vicariously through identification with the power of the state, a corporation, or in the case of 1930s Germany, a fascist dictator. Using phrases like the "eruption of mass hysteria" or a "mob mentality" may describe what appears to have happened, but they do not explain what actually happened. Reich's explanation (like Adorno's and Habermas') looks to the structure of the personality of the individual, and especially to the emotional dynamics of the patriarchal and sexually repressed authoritarian family that produced them. This kind of "sex-economic analysis" that combines Marx and Freud was picked up in the 1960s and came to characterize the feminist and progressive Left.

Yet, with that said, achieving sex and gender equality is *necessary but not sufficient* for a sustainable and peaceful society. Patriarchy is only *part* of the problem. In the post-industrial West (in the core states of the capitalist-world system), women are for the first time in history outperforming men in attaining college degrees (NCES, 2018). Much remains to be done, but progress here is notable, especially in the United States. However, we must also note that 45% of all college-educated women in the US voted for Trump, the majority of whom described themselves as "angry" (Wilber, 2017). Economic injustice for women remains and is made more painful by the debts accrued in pursuit of "equal access" to education, as college degree attainment reflects economic class more then gender (*Ibid*). More importantly, even in a society that has shed a great deal of the traditional family, gender roles, and identity structures, whole populations are still voting and acting against their own economic and political interests. The point here is that even with the gains made in the wake of the 1960s gender revolution and the broader civil rights revolution, we are currently facing an even more profoundly distorted deep structure of emotion which is tending in authoritarian and conservative directions (Apple, 2001; 2013). We are still murdering Eros, just in new and more sophisticated ways.

Culture Evolves: From Role Mates to Soul Mates and Beyond

The suppression of the erotic has taken a new form in the market democracies of the Western world, which are striving for gender equality and a new sexual ethics. The loss of happiness in market democracies has been well documented, where it is clear that money, safety, and all the trappings of conventional success do not bring lasting happiness (Lane, 1991; 2000). The capitalist colonization of the emotional dynamics of the family has continued into the twenty-first century, even if some of the overtly patriarchal dominance has faded. In a large and growing number of American households, women are the predominant breadwinners, and men are dependent economically. Couples stay together not because of conformity to traditional roles (at least not only), but rather because they are "in love." Contemporary couples are not merely "role mates" sanctioned by a traditional culture; they are "soul mates," standing outside of traditional cultural norms (Beck & Beck-Gernsheim, 1995). *A Return to Eros* draws attention to the recent evolution from a culture of patriarchal role mate relationships to a culture of matriarchal soul mate relationships. Beyond the soul mate is a more evolved whole mate, a higher level of relationship that Gafni and Kincaid posit, and which I discuss further below. The distinction between role mates, soul mates and whole mates is one of several key cultural distinctions within *A Return to Eros*.

The soul mate liberates us from a cultural narrative that revolves around the role mate. As poetry, music, and devotional literature the world over reveals, the power of the soul mate relationship to heal, grow, and enliven is simply exquisite. Where the role mate fits into conventional cultural norms, economic necessities, and the realities of running a household, the soul mate lifts one out of these mundane trivialities entirely. Finding your soul mate can feel like a lightning bolt of erotic energy that hits you out of nowhere, and it can change the way the rest of the world looks. Importantly, when Gafni and Kincaid use the word "soul" in this context, it is not in any rigorous theological sense. Here the soul mate is taken as a cultural category, not a metaphysical one. Therefore, some connotations that the word holds for some readers will not be appropriate. The soul mate relationship should be understood as a result of modern cultural evolution, emerging from new economic conditions and changing norms and representations about the meaning of romantic love. This means that the soul mate relationship is susceptible to becoming distorted and co-opted like any other relationship. Even the best innovations in cultural evolution are only appropriate for a certain phase of evolution. Part of the narrative offered in *A Return to Eros* is about overcoming the limitations and distortions that have come to characterize the culture of the soul mate.

For example, there is a widespread idea that one's romantic partner is what "makes it all worth it." This is a novel idea related to the emergence of the soul mate relationship during cultural modernity. Taken to its extreme, this idea dictates that the soul mate should be the only source and focus of all of one's erotic energy. The soul mate is one of the few things culturally validated as being more important – emotionally, erotically, and energetically – than anything else in someone's life. The soul mate in our culture holds more erotic focus and expectation than it can possibly bear. It must make up for de-eroticized work, de-eroticized consumption habits, and de-eroticized entertainment. Remember this is not about what the culture industry sells as "sex," where a great deal of our money and attention is spent. The core issue in thinking through sex-economic critiques of existing structures is the quality and availability of erotic emotional experience outside of the sexual. Where in the culture is one able to invest all of one's energy? Where can one tap the powder keg known as the limbic system and really open the gates of emotion? For many people in our culture, the answer is their current (or hoped for future) soul mate, for whom and with whom self-transcendence, self-sacrifice, merger, and fulfillment are possible. The beauty, truth, and goodness of this form of relationship is what drove a revolution in culture, starting with the Romantic era's reaction to the beginnings of modernization and continuing through to the "Summer of Love" in 1967. The emergence and cultural propagation of the idea and value of the soul mate relationship constitutes a fascinating study in the evolution of consciousness, which *A Return to Eros* only begins to tell (see: Gafni & Hubbard, forthcoming).

Our culture is focused on the beauty, specialness, and intensity of the soul mate relationship. While this culture of soul mates involves a radical questioning of the role mate, it is still a culture that requires a profound truncation of Eros. The intense value of a soul mate relationship has the power to break the molds put in place by a culture of tradition and convention. But a life of dedication to one's soul mate remains a truncation of the erotic. This is true even when you have numerous soul mates – even if you have them at the same time. As Gafni and Kincaid are clear to point out, the issue of expanding the erotic beyond the culture of soul mates is not about the issue of monogamy versus polyamory, although this is an important issue. The issue is about the exile of our most potent and foundational emotional energies and experiences entirely into the domain of dyadic personal relationships, and within that domain, entirely into sexual relationships. A potent negative image here is of the bubble of shared narcissism that surrounds soul mates staring into each other eyes, oblivious as the world burns around them.

A Return to Eros posits a new ideal for love and intimacy in an age of fracture, which transcends but includes the culture of soul mates. This vision is a first step towards reworking the emotional deep structures of our culture. New human potentials only manifest in the context of new forms of relationship. The love stories we tell in our culture today are mostly about soul mates. Can these be retold in the context of a larger love story that transcends but includes the soul mate narrative? Can we place our individual love stories within the larger love story of the universe itself? These are the questions driving *A Return to Eros.* Before the ideal of the "whole mate" can be discussed, a larger story must be told about the evolution of the universe and humanity. Evolution at all levels has proceeded through the emergence of new forms of complexity and intimacy; this has continued though the evolution of human culture, which has also moved "upward" into increasing degrees of complexity and intimacy. We now stand on the verge of a breakthrough in relationships and community on a planetary level (Stein & Gafni, 2015). Part of this evolution is the emergence of a new story about human love and the forms of social life that honor the profound realties of our emotional being, a story that makes clear the relationship between human ethics and the rest of the evolving universe.

Ontology NOW! Getting Back to Reality

The sections in *A Return to Eros* that fall under the heading of the "cosmo-erotic universe" may be the most important. This is where sex and politics merge with the third and most dangerous topic: *reality*. Beyond all the stories and Biblical myths, beyond the analysis of sex, Eros, and relationships, *A Return to Eros* is putting forth a specific conception of reality. The basic claim is that the bio-psychic energies of the human are continuous with those of the universe itself, and thus manifest the same patterns, qualities, and powers. This is a simple truth about the radical interconnectedness of each human with the totality of the cosmos. We are made of stardust, through and through (Bruteau, 1997). These kinds of realities can mean nothing or they can mean everything. To paraphrase Einstein: you can see everything as a miracle, or you can see nothing as a miracle. *A Return to Eros* is about seeing everything as a miracle, especially the potential for human manifestations of "evolutionary love," a form of emotional life continuous with Divinity itself. Metaphysically speaking, *A Return to Eros* is describing the lived experience of Gafni's (2012) *acosmic humanism*, which has been expanded into a comprehensive *cosmo-erotic humanism*. This is based on an ontology that locates the identity of human and divine action in the erotic enfoldments and emergence of evolution itself. This ontology suggests an expansion of our capacities and identities beyond the skin-encapsulated ego, while also managing to fit within the assumptions of leading-edge evolutionary theory.

The question of just what counts as leading-edge evolutionary theory brings us to the point of this section. Getting a handle on reality is hard these days. There are no longer just a handful of authoritative academics working at the frontiers of evolutionary theory; there are over a thousand of them. In the past 50 years, the acceleration of academic knowledge production in the departments of biology, biochemistry, and environmental/ecological sciences (all fields dealing with evolution) has taken an almost exponential curve. Areas within the field show consensus on some issues, but whole populations of scientists disagree about foundational axioms, the interpretation of key findings, and the meaning of basic concepts (Capra & Luisi, 2014). Then there are the individuals who serve as pop-science mouthpieces, shouting into the public sphere about how evolution works as if there was scientific consensus, when what they are actually doing is only thinly veiled apologetics for predatory capitalism and abstract possessive individualism. Standing in opposition from pop-science are the think-tanks and industry skunkworks focused on complexity science and applications of evolutionary game theory and competitive landscape modeling. But who has the *real story* about evolution and the nature of the human? Of course, even after all of the academic debate, what really matters may be the Google rank and Wikipedia page of various evolutionary theories, as this is where the majority of students and non-specialists are forming their ideas. The state of scientific knowledge has fragmented beyond the possibility of any near-term synthesis, while at the same time it is being simplistically funneled through Goolge and Twitter.

This raises a general question about our culture: If you can't find it on Google or fit it into a Tweet, is it true? Serious cultural critics have to ask if it even matters if something is true or not anymore (Wilber, 2017). We live in a post-truth culture where positing the reality of anything is difficult. *A Return to Eros* can only be taken as poetry in this kind of context, yet Gafni and Kincaid are offering truth claims. Today ontological truth claims are unfortunately so mired in caveats that they mostly cease to serve a function in language (Habermas, 2009). In the interest of overcoming the fallacies of the modern mindset, the postmodern mind sought to put an end to "truth," and has now hit the jagged edge of its deconstructive projects, something reflective educators have seen coming for decades (Gardner, 1999).

What fanned the flames of academic deconstructionism into the raging wildfire of our post-truth culture? In part it was the computer technologies built by the cultural elite, which are still being marketed as if they will usher in an age of universal education and democracy, when they have demonstrated they do exactly the opposite. This is not the place to outline the failures of social media and search engines as educational technologies, let alone as technologies of socialization (Stein, in press). But regardless of the platform, the popular appeal of relativism stems from its political power. The weaponization of rumor is now an accepted political strategy. Seeking to short circuit the relations between *power and knowledge* (i.e., seeking to undo the use of knowledge as a tool of oppression wielded by elites), postmodernism decided to do away with knowledge itself (Foucault, 1980). Predictably, the result is that only power remains and discourse devolves into rhetoric and posturing, or worse, name calling and scapegoating.

To take only two examples from the upper echelons of academic culture, Yale University's Keller Easterling is a widely influential critical theorist in the fields of architecture and design. She explicitly suggests lying, rumor, and hoax as political strategies that can aid or hinder the creation of certain infrastructure projects (Easterling, 2014, pp. 215-218). I also cite Hebrew University's best selling historian, Yuval Noah Harari (2017, p. 206), who argues essentially the same thing. Both claim that stories are tools, and therefore the truth of a story has less importance than its political impact. As Easterling (2014, pp. 215-216) says: "Rumor and gossip [are] tools of aggression among the powerless." She argues that they are also available to the powerful and can become "a practical technique of markets and governments." It sounds like she is setting up a critique but she is actually suggesting that everyone play along: "[T]he environmentally sensitive designer might also embellish [their ecological design plans] with a narrative rumor – mixture of fact and fiction or what Hollywood calls 'faction'" (p. 218). Easterling's strategic retreat from narratives based on fact to narratives based on "faction" leaves designers with no choice but to retreat into actual political factions as a kind of retribalization. When the idea of a possible truth that might reconcile differences dissolves, all that is left are power games. The culture has been veering away from strong and commonly held conceptions of reality and truth and growing to accept the spreading of untruths for the sake of in-group solidarity. The periodic eclipse of reason is part of the evolution of civilizations, usually cascading into an age of fracture and barbarism (Rodgers, 2011; Horkheimer, 1947).

The new post-truth culture is most obviously dangerous when it comes to orientating collective action towards the realities of the physical world. It is simply dangerous to not have a clear sense of the effects of common industrial toxins and food additives, the scope of climate change, or the amount of radiation leaking from the damaged Fukushima nuclear reactor. It is more comfortable to see post-truth culture as a problem contained to things like tabloids and contentious presidential politics. According to this view we can simply set up a Google "fact checker" without ever settling the tricky problem of what constitutes a fact or truth (Wilber, 2017). The issue is much deeper then celebrity gossip and lurid political mudslinging.

The post-truth culture is predicated on the following accelerating trends in the new informational ecosystem:

1. the inability to distinguish non-commercially motivated from commercially motivated information;
2. the related inability to distinguish honest information from intentional misinformation that is spread for strategic advantage;
3. decreased message length, increased message frequency, and inability to track all message sources (i.e., information overload);
4. the absence of shared overarching meta-narrative that could potentially reconcile conflicting information and perspectives;
5. escalating emotional intensity of information (due to factors 1-4);
6. weaponization of language, (i.e., lies, slander, censorship, politicization, due to factor 4).

Micah White (2016), who was one of the key architects of Occupy Wall Street, discusses these trends from the perspective of the interface between politics and social media, where now the *representation* of the political takes precedence over actual politics. David Healy (1996; 2002) and Robert Whitaker (2015) discuss the same phenomenon in the fields of medicine and psychiatry, where the profit motive is systematically distorting research and public information campaigns. The same dynamics have caused a breakdown in discourse surrounding the reform of public schools in the United States, as the politicization of testing and the occurrence of widespread cheating has created disinformation, intense animosity, and a "chamber of echoes" (Ravitch, 2013; Schneider, 2014).

The unstated implication of this research is that political and psychological *realities* are hard to get good information about, especially if you only want to look at a screen to do so, let only if you only want to look at one social media platform (which is the norm, especially for those under 21). Identities as we have known them are disappearing, dissolving in the chaotic noise of the information age (Thompson, 1998). One way to think about *A Return to Eros* is as addressing the self-understandings of the species: are we lovers and creators or fighters and competitors? The book seeks to avert an impending species-wide identity crisis by counteracting the disintegration of the cultural resources that humans have traditionally used to create identities, relationships, and political communities. It reminds a post-truth culture that *reality matters*. Getting back to reality means embracing a new kind of metaphysics (an integrative evolutionary *realism*), a paradigm that is still being explicated at the leading edge of metatheory (Bhaskar, Esbjörn-Hargens, Hedlund, & Hartwig, 2015).

Realism about the exterior and physical argues for the existence of laws of nature, facts, processes, and tendencies in the universe (Bhaskar, 1993). Realism about *interiors* argues these same points for the life of the mind, demonstrating the existence of laws of nature, facts, processes, and tendencies in the domains of the psychological and cultural (Stein, in press). Taking seriously the ontology of human interiors means looking at the evolution of consciousness as well as the structures and dynamics of emotional energy. Both forms of realism (exterior and interior) are implicated when you want to make sense of the human in an evolutionary context. This is precisely what is so powerful about evolutionary explanations of human actions: they ontologize our humanity, making us feel at home in the universe (Kauffman, 1995). Evolutionary explanations give a deeper, broader, and more coherent sense of the reality of the human experience, which is today too often characterized as if it were merely a social construction. I believe that it is actually impossible to live in a culture and with an identity that reflectively takes itself as an arbitrary and meaningless construction. Humans need to orient around a sense of the world and their place in it that they believe is true. This means looking at the realties that underlie both the natural world and the human lifeworld.

Cosmo-erotic humanism offers a new kind of story about the universe, one that seeks to make good on the promises made by the complexity sciences more than a decade ago (Wilber, 1995; Kauffman, 1995; Capra, 1996). *A Return to Eros* is about the interior dimensions of increases in exterior evolutionary complexity, which are increases in consciousness, creativity, and Eros. These five trajectories of evolution (*complexity*, *consciousness*, *creativity*, *uniqueness*, and *Eros*) are reflected in the trajectories of individual development (Gafni & Kincaid, 2017 pp. 199-202). The universe evolves towards more complexity, consciousness, creativity, uniqueness, and Eros, and so does each individual within it. Humans can become aware of this reality, and so begin to self-consciously steer themselves into the strong currents of the evolutionary stream. This is an ontological claim, not mere poetry offered into a post-truth culture. This conception of reality is not abstract; it has direct relevance to the ethics and politics of relationships. It is at this point that the ethics of the *whole mate* can be understood.

A Return to Eros gives a vision of relationships that transcend but include the ethics of the soul mate, bringing forward the possibility of intimate love relationships that expand the energy they generate outward; these are unique love stories that open outward and into a universal love story. This is a call to expand the flow of Eros that is now limited to the options of a commoditized culture of soul mates. Where soul mates feed the wedding-baby-vacation-industrial-complex, whole mates understand the evolutionary and world-historical context in which their relationships take place. Love is the exception and escape from a troubled world where soul mates *retreat* into each other’s embrace, taking an “us against the world” stance to defend their shelter of love. For whole mates, love instead becomes the power to *engage* and heal a troubled world. Whole mates work together looking with eyes to the horizon, knowing their shared love participates in a universal evolutionary love. Where soul mates feel compelled to join genes through sexuality, whole mates may or may not engage sexually, and instead feel compelled to *join genius* in an erotic embrace beyond the merely sexual (here Gafni and Kincaid are drawing on the work of futurist Barbara Marx Hubbard). Whole mates are likely to join triadic or ever larger configurations of intimacy and perspectival coordination. The knowledge and experience of whole mates is of love as a force of nature. This vindication of the ontic reality of love (what Bhaskar (2012) would call *the alethic truth of love*) is the greatest message of *A Return to Eros*. Humanity is at home in the universe because we are at home in the reality of love. Love is not merely poetry or romance. Love is Eros, the actual driving force of cosmic evolution itself. This reimagining of relationships is the key to bringing culture back to reality.

Conclusion
Love in the Anthropocene: Life Without Externalities

I have argued that *A Return to Eros* contains fragments of a new psycho-sexual-spiritual critical theory of self and society. This is part of a larger project of *cosmo-erotic humanism*, which is itself part of a broader return to metaphysics that constitutes a metamodern worldview. This paper has only partially pieced some of these themes together. I began by recognizing the unique condition of metamodern metaphysics and arguing that doing metaphysics is now necessary because of essential changes in the human condition. The methods of metaphysical inquiry have changed along with the topics that ought to be the focus of metaphysical speculations. There is no longer any prospect for premodern forms of metaphysics after Kant, Darwin, and planetary-scale computation. Yet the modern and postmodern *absence* of metaphysics has created its own problems by leaving a vacuum where answers to the most important questions used to be found. The metamodern return to metaphysics seeks to fill this vacuum of meaning by providing a new context for human self-understanding – a new Universe Story that includes a new story of self and community. *A Return to Eros* offers part of this new story, focusing especially on our most intimate relationships, on love, and only beginning to outline the implications for politics.

Gafni and Kincaid argue for the primacy of emotional life and for flipping the typical prioritization in Western culture; here they are pointing to the emotional “tail” that wags the cognitive “dog.” The source of emotional life itself can be understood in terms of the cosmic dimensions of the bio-psychic energy contained within human sexuality. Sex is the great secret that evolution has placed within the core of human emotional life. Tantra is about *the clarification and expansion of erotic desire beyond the sexual*. This is about repurposing the powder keg of the system, not defusing it. Cultures have historically sought to defuse the cosmo-erotic nature of humanity. Individuals embody the limited forms of Eros enabled and validated by their cultures. Events in recent political life and public culture have demonstrated widespread distortions of emotional structure, which are manifesting in patterns of behavior long familiar in the history of capitalist civilization. Reich (1969) demonstrated that people will vote and act against their own material and political interest because of basic distortions within their emotional lives, specifically the truncation and misdirection of erotic energy. Gafni and Kincaid take this argument one step further by stressing the Tantric expansions of the erotic beyond the sexual, which allows for a critique that applies across both the Right and the Left of the political spectrum. The overt repression of sexuality has been the traditional conservative root of emotional dysfunction, and while Western cultures have overcome much of this overt repression, the result has been a different kind of erotic truncation. Where sex is not repressed it is hypertrophied; instead of a culture arranged to avoid sex, the culture is arranged to focus directly on sex.

Advertising and entertainment are only the tip of the iceberg; whole economic sectors are now built around a culture of romance in which we are told to prioritize seeking our soul mate. Culture sanctions the soul mate relationship as the highest form of intimacy. However, there are possibilities within the soul mate relationship that allow lovers to get caught up in a logic of *externalities*. Building, maintaining, and protecting our shelters of love can lead us to place ourselves outside the world. Commodification is based on this logic of externalization, where the desire to improve the quality of local short-term experiences blinds us to the long-term and distant consequences. We externalize waste, risk, labor, and the rest of the full impact of our lifestyles. The capitalist world-system has operated according to this logic on a grand scale for nearly 500 years, externalizing the impacts of economic growth by moving waste around the world and its fallout into the future (Wallerstein, 2006). The culture of soul mates, which was brought to fruition by the revolutions of the 1960s, has since been largely co-opted and is now a potentially counter-revolutionary force.

A Return to Eros argues that there are forms of intimacy that transcend but include the ideal of the soul mate. These make possible a new kind of culture and new structures of emotion, thought, and action. It is possible to access a universal evolutionary love (i.e., the *cosmo-erotic qualities of human emotion*) that expand love beyond sexuality and allow the qualities of Eros to suffuse all aspects of life. The soul mate relationship can be transformed into an amplifier of evolutionary love as it evolves into a whole mate relationship. In the process the logic of externalities falls away. The reality of the human situation dawns on us (with huge political consequence): no one individual love story can be played out separately from any others. The experience of Eros lifts the focus of the soul mates beyond themselves and into a total embrace of humanity and the universe. Nothing needs to be bought to prove this love. There is no vacation spot where it might be improved. Evolutionary love expands outward; the love between two soul mates is transformed into an act of theurgist protest, a kind of mystical activism that draws on humanity's capacities to manifest universal (super)natural forces (White, 2016). The image here is of a world historical *revolution of love* (Bhaskar, 2012), made possible by the evolution of new forms of relationship and intimacy.

Of course, any attempts to forge new forms of relationship will be seen as dangerous. The nexus of sex, reality, and politics remains a dangerous place to innovate. Living a life without externalities – a life that extends love to all relationships – requires looking into the social realties of the global commodity chains, political networks, and communication infrastructures we live within. Living a life dedicated to evolutionary love instead of romantic love is an utterly simple act of total subversiveness. Romanic love has the power to free individuals temporarily from the suffering of the world, but it does not have the power to free the world from suffering. Therefore we must evolve through and beyond the culture of soul mates and towards forms of relationships in which we can live as unique incarnations of cosmo-erotic love. Whole mates are amplifiers of evolutionary love. This new form of relationship is predicated on seeking to embody the force of Divine Eros itself in all aspects of our lives, not only with those chosen few souls we take as special. This means you can no longer leave Eros at the door when you go to work, go shopping, engage with social media, or join a protest. It means the end of the substitute gratifications and distorted expressions of erotic energies that drive so much of today's cultural industries. It means that no one or few are taken as special and set apart. Instead, all are taken as unique, and no one is ever placed outside the circle of concern, tolerance, and compassion.

Cosmo-erotic humanism is not offering an indiscriminate love-fest or a self-contradictory relativism that claims to love everyone only to then put on displays of hate. It instead offers a return to reality. Metamodern metaphysics needs find a way to get beyond the limits of post-truth culture, which means finding ways to embrace non-pathological value hierarchies of truth, goodness, and beauty. We should seek ways reverse the tendencies of love to contract inward and shrink in this age of fracture. As things are going now we are deepening the fractures, retreating into a process of multiplying the “others” and partitioning off our safe spaces. We are shrinking love down to a small circle, while lashing out at an ever-expanding circle of the unloved in the world beyond our screens. This logic of keeping love and respect for “us” and saving none for “them” reflects the truncations of Eros that so often burden and distort human personalities. The emotional structures of humanity will need healing if we are to again take up the quest for mutual understanding and put down the quest for mutual destruction.

The pursuit of mutual understanding between people who disagree is the key to anything like a society worth living in. Not, “you have your truth and I have mine,” but rather, “we live under a common truth that we are seeking together.” The collective pursuit of mutual understanding is not about condoning hate and ignorance by equally valuing all voices. Seeking understanding does not mean reaching an agreement. It is a reciprocally *educational* process that must be sincerely engaged by all parties. Some may be too full of hate to be open to learn, but we must love even those who are hateful in order to see into the reality and humanity of their lives. Justice requires seeking ever new ways to counter hate with love. The desire to seek mutual understanding is not the result of cognitive insight. It is an embodied emotional disposition and a presupposition of discourse (Habermas, 1998). This makes it something that is not the result of discourse, because discourse is not even possible if we don’t already agree to seek mutual understanding. This means that the task of restoring any semblance of reason to the public sphere is first and foremost about addressing the structure of emotions, specifically the material and cultural conditions that are generating widespread distortions and truncations of Eros.

I began this paper writing about the eternal battle between Eros and Thanatos. I suggested that our historical moment is one in which this battle is raging out in the open. According to everything I’ve discussed so far, it may seem that Thanatos appears as a frightening glitch in the matrix of Eros. How can those who believe in the ultimate reality of love face down the reality of hate? How can a universe fueled by Eros even make sense in the face of what Thanatos creates? Thanatos creates a torrent of malice, spite, and sadism that slaps the face of anyone offering simplistic notions about the basic goodness of human nature. Thanatos is worshiped by the likes of Nick Land and those who are seeking a reality beyond relativistic and irrational world cultures of post-modernism. We must be aware of the tendencies and evidence in favor of holding humanity in the context of a new “dark” metaphysics, which could form the backdrop for a metamodern politics with profoundly negative consequences.

The current cultural impasse cannot be resolved through the unforced force of reasonable words, which is why many believe that it will be resolved by actual force. What is certain is that only large-scale and significantly forceful actions will suffice to change our course. I believe drastic action is needed that focuses specifically on changing the basic conditions in which the human heart is shaped. Practices that demonstrate the full reality of Eros are profoundly transformative for those who would otherwise hold a simplistic and negative picture of human nature. A totalized educational revolution is needed, starting with the schools and media and expanding outward to refashion technology and the economy itself in the interests of healthy human development (Stein, in press). *A Return to Eros* provides only some of the frameworks necessary for addressing this task of a total educational revolution in the interest of love. There can be no future in which humans are taught and socialized into the narrow confines of national and economic self-interest. The only future possible is one in which love and justice are the cornerstones of global educational systems. Not systems that teach *about* love and justice while treating children and adults inequitably, but rather educational systems that *demonstrate* love and justice in their total support for the free development of children and families, up to and including basic income guarantees and health care. This will mean that the priority for global futures is *love*, not profit and growth or sustainability. Profit, growth, and sustainability mean nothing if they land us in a world without love. Cosmo-erotic humanism argues for a planetary prioritization of love and for securing the necessary and sufficient conditions for the possibility of love. These are some of the most important implications of what I have been discussing here as a metamodern return to a metaphysics of Eros.

Awakened Perception: Perception as Participation

Bonnitta M. Roy[1]

Abstract: Perception has been called into questions by eastern traditions and western scholars for millennia. In a few “secret” places in Zen, Chan and r-Dzogchen Buddhism, the ultimate valid truth is said to be directly perceived. I propose a modern methodology called *integral phenomenology* that integrates deep phenomenal examination with contemporary research on perception (from both eastern contemplative science and western empirical science), to reclaim the notion of direct perception as *adequate participation*. In doing so, I develop an ecological model of perception, which includes “hybrid zones” where different perceptual states overlay each other, leading to non-ordinary experience, state transitions, and eventually, self-liberating insight and non-dual wisdom. This modern methodology must pass the critical examination of the highest Buddhist authority on direct perception—the Gelukba Sautrantika school. This is a critical challenge, and yet, if successful, shares the Sautrantika’s schools optimism that liberating wisdom can be gained by starting with everyday ordinary experience—which is a key principle of the integral phenomenological method.

Keywords: Direct perception, kensho, integral phenomenology, participation.

Author's Preface

What you have below is my thesis for a Masters of Arts in Consciousness Studies at The Graduate Institute in Bethany, CT. The editors who reviewed it and I all sensed that as such, it could benefit from a comprehensive reorganization, but none of us could actually envision what that would be. Instead they suggested I write a preface to help orient readers. Foremost, the reader should know that this thesis unfolds itself as it follows my own ongoing inquiry and discovery of research that is new and surprising and calls for a radical re-visioning of what it is to perceive. Although it has been a year since I submitted my thesis, I am still pondering its implications as well as finding a new sense of wonder in perceiving the natural world. Therefore, it would not surprise me if, at the end of the paper, you might feel you have just begun a similar exploration, hopefully now with a few more signposts to help you carry forward what has been started.

Guiding Inquiry

The hypothesis beneath this work is that a modern minimalist approach to awakening, can accelerate conscious transformation. In this approach, "awakening" is defined as *awakening to the nature of experience.* This paper focuses only on one of the four[2] key aspects of experience: perception.

My guiding question in this paper:

> *Can a model of perception based on participation pass the critical examination of the Buddhist traditions, complement neurophysiological research, and support meaning-making around first- person accounts of ordinary and non-ordinary perceptual experiences?*

My guiding purpose in this work:

> *To develop modern approaches and heuristics to accelerate transformations of consciousness toward re-enchantment with the world, and to create conditions for people to flourish and the planet to thrive*.

Methodology: Integral Phenomenology

The Wiley Blackwell Handbook of Transpersonal Psychology (Friedman & Hartelius, eds. 2015) includes a section on future directions for transpersonal research. In it, Rosemarie Anderson and William Braud (2015) highlight *three* approaches that are particularly suitable for transpersonal research: *intuitive inquiry, integral inquiry, and organic inquiry*. My approach, which I term *integral phenomenology* borrows from all three approaches in the following ways.

1. From intuitive inquiry
   a. reflecting on extant topical texts and developing the preliminary interpretive lenses
   b. transforming and refining interpretive lenses

---

[2] The other three are: affect, tacit knowing, and virtual perceptions (inner hearing, inner images, inner taste, inner smell, inner touch, and other simulations of perception).

2. From integral inquiry
    a. the goal of acquiring both knowledge and wisdom
    b. interest in transformative knowledge
    c. whole person involvement
    d. integrating a spectrum of modes of knowing: sensory impressions, words and thoughts, images, feelings, intuitions, realizations in altered states of consciousness, sensorimotor modes, and direct means (becoming the object of knowing)
    e. integrating sources of inspiration, including the natural sciences, psychology, sociology, anthropology, philosophy, literature, the arts; as well as spiritual wisdom and folk traditions; and personal and anecdotal evidence.
3. From organic inquiry
    a. focused on transformative validity, i.e., the thesis as
        i. an "evocative vehicle of feeling as well as thinking
        ii. presenting a diverse and intimate view of the topic
        iii. in order to engage the individual reader in a parallel process of transformative interpretation

In addition to the above, *integral phenomenology* relies on the research data from the field of neurophenomenology as a source of valid interpretation of direct, phenomenological inquiry. (Laughlin and Rock, 2015). As a methodology of research, *integral phenomenology* rests on four axes of validation: 1) adequate participation with the topic through direct, phenomenological inquiry, 2) corresponding or confirming evidence from the neurosciences, including neurophenomenological evidence, 3) an individual, collective, cultural or political transformative potential, and 4) purposeful action-inquiry toward *the good*. A rubric for addressing these four criteria is what I call the 4-A's (Forays):

1. Appeals to our deepest spiritual intuition
2. Available to scientific inquiry
3. Politically Actionable
4. Aesth-ethically beautiful

Part I: Discovery

Introduction

This paper is part of a larger project on what I call integral phenomenology. Integral phenomenology is a methodology for people to become aware of the nature of experience. This approach examines the micro-states, micro-stages, and micro-genesis of experience along four foci of inquiry: affect, perception, tacit knowing, and inner perceptions. It provides a foundation for embodied, contemplative practice as an inquiry into the nature of thinking, turning metaphysics into a direct examination of the architecture of thought itself. Integral phenomenology combines a direct examination of lived experience in contemplation and vipassana meditation, with contemporary neuro-cognitive science and neuro-affective science. Its larger, "big picture" interpretive framework includes the three narrative sciences of development, anthropology and evolution. The ultimate goal of integral phenomenology is for individuals to shift from the passive modes of experience, to their active, enlightened modes. When the modes of experience remain passive, highly conditioned and habituated, the person expresses socially conventional, self-referential, neurotic forms of behavior, that are primarily driven by unconscious impulses and reactive tendencies. Awakened modes of experience provide the basis for enlightened action in the world, which is post-conventional, other-referential, compassionate, and open to more degrees of freedom, in awareness, intention and choice. Activating the modes of experience means shifting affect to intuition, perception to insight, tacit knowing to open participation, and inner perceptions to creative imagination.

First, by disentangling the modes from the knot of phenomena and stimuli that constitute conventional experience, we can begin to examine their underlying dynamic patterns and processes. This can be done by integrating phenomenological methods of inquiry, with scientific, philosophic, and narrative works associated with them. By going back and forth, from reading about a specific experiential mode to direct inquiry of that specific mode, through phenomenal examination of ordinary experience, integral phenomenology builds a greater understanding of and deeper capacity for directly observing phenomena at finer and finer details. Together, these accelerate personal transformation.

The focus of this paper is on perception-- its micro-state, micro-stages, and micro-genesis. I will explore how perception can shift from its conventional, passive role to a more awakened, active role called insight. I will explore the notion of direct perception as a sustained open awareness of one's lived experience as direct participation. This direct participation includes interactions among the multi-modal perceptual organs within the body-brain-mind of the person, as well as interactions between the person and the living world. In enlightened states of perception, we have the insight that the perceptual organs and the living world are not two, but one larger ecology, in which myriad phenomena emerge through dynamic participation, eventually giving rise to innumerable subject-object definitions at the terminal end-states of experience.

Perception has been called into question by scholars, philosophers, and scientists, and by spiritual traditions for more than 2500 years. This has led to paradoxical conclusions. On the one hand, everything we can know about the world relies on some mode of perception. And yet, we are all familiar with many ways in which perception succumbs to error and illusion. We delight in perceptual illusions of all sorts, and are dumbfounded by experiments like the Gorilla, who saunters across the basketball court, hidden in plain sight[3]. Science has the tools to prove perception wrong, but every one of its tools ultimately relies on some mode of perception to get to that proof. Whether we use the scientific method to correct and revise, or question and replace ordinary sensory information, we must concede the fact that in the process we are also *simultaneously confirming our confidence in our own ordinary senses*, since all empirical science ultimately rests on ordinary sensory observation – whether that is a blip on a computer screen, sounds from a recorder, or colors on a photographic plate.

Time and again we are reminded of the failures of the eyes to directly see and the ears to directly hear what is actually happening in the real world. And yet, athletes are capable of extraordinary feats that would be impossible if the senses were not operating perfectly in tune with reality. We are told that perception biases the self, and yet, it is in certain states of flow, or when under extreme conditions and outrageous challenges, when the sense of self is absent, that perception performs in optimal ways.

---

[3] See the *Invisible Gorilla* at http://www.theinvisiblegorilla.com/gorilla_experiment.html

Spiritual adepts of the east tell us that all we can perceive is but an illusion or a dream, but their behavior tell us otherwise, since they all performed as if the perceived attributes of experience were real. In the western philosophical tradition, we see more of the same. David Hume, for example, declared that there was no reason to believe the perception that it was preferable to walk out a building on the first floor rather than from the third. And yet, he never walked out of the third floor window.

Kant said that perception had to be overcome by the use of cognitive faculties that transcended the phenomena, and the postmodernists have argued that all perception linguistically and culturally mediated (de Zengotita, 2008); while Johnson and Lakoff (Johnson 19787; Lakoff and Johnson 1999; Lakoff and Nunez 2001) have argued that all cognitive and linguistic faculties, including logic and mathematics, ultimately derive their meaning from embodied modes of perception.

In this paper I hope to resolve these paradoxes through the notion of perception as different configurations of participation. In each experience we can ask ourselves "What are we participating with?" In some cases, the participation will involve memories, fantasies, worries, cognitive and culturally conditioned biases. In some cases, the participation may be pared down to raw data streams interacting with neural cells, as for example, light exciting retinal cells. In between there is a huge spectrum of variation, depending upon what levels of experience are "in play" and which are absent, determined by what aspects of perception are "online" and which are "offline."

Here the notions of hyper-trophy or amplification and hypo-trophy or attenuation of perceptual streams are important considerations. They are associated with the neuroscience of perception which demonstrates that perceptual experience is determined by complex global dynamics that emerge from excitatory and inhibitory feedback processes in the brain. This dual relationship, between excitation and inhibition explains the complex causal relationship between perceptual experience and non-ordinary states in meditation practices and scientific exercises designed to elicit them.

For example, exciting some areas of the brain inhibits the activity in other regions, but these other regions may themselves have inhibitory effects on different areas, which has a net effect of *exciting them*.

We shall also see that each perceptual organ (defined as the sensory organ and its associated body-brain networks) interacts in multiple complex ways with others to produce variations of perceptual experience. Furthermore, every perceptual experience is associated with a discrete "subject" or "sense-of-self" that is partially determined by what aspects of perception are amplified, attenuated, or absent. This sense-of-self constitutes the phenomenon that cross the threshold above the unconscious perceptual processes. These three correlations: 1) the aspects of perception that are “in play” at any given moment 2) the excitatory and inhibitory feedback interactions among them, and 3) where the threshold of self-consciousness happens, can be shown to delineate as different states of consciousness that have been described by spiritual traditions, and identified by neuroscience as discrete brain states. This will enable us to derive a *definition* of *direct perception*, or more accurately, of *sensory clarity*. I will argue that sensory clarity is *awakened perception*, and that it is a key credential to any claim of enlightened awareness.

Sections of this paper describe my own journey towards a better, more robust understanding of unconventional, non-ordinary perceptual states that I have experienced at different times in my life. I interweave my own stories with accounts that appear in the literature resources I have incorporated into my research. In the final section of the paper I subject my work to a critical examination to the framework of direct perception developed by the Sautrantika scholastics of the Gelukba tradition, considered one of the most advanced examinations of perception.

A Brief History of Perception

Countless arguments have been made calling perception into question. Some of us are aware of the eastern religious traditions which claim that all perceptual phenomena are illusory. The Sanskrit term “Maya” involves a rich and complex history of meaning around the illusory nature of experience, warning us that reality does not exist as it appears, that perception is peppered by error, confusion and ignorance, that the mind veils, the emotions cloud, and thought obstructs perception in ways that deliver a false impression of reality. In the eastern traditions, this false impression is blamed for the human condition of *dukkha*, our ordinary state of suffering which is called *samsara. Samsara* is contrasted with *nirvana*, the enlightened condition associated with the cessation of suffering. In the enlightened state a person is said to be able to *directly perceive the true nature of reality*. Still, what is revealed *as reality’s true nature* differs quite dramatically among the traditions. Some traditions, such as Hinduism and certain “mind-only” schools of Buddhism describe the true nature of reality mostly in mystical, metaphysical or idealist terms.

In contrast, other traditions, such as Daoism, Hua-Yen or Chan Buddhism in China, and Zen Buddhism, seem to describe reality in ways that remind us, as western readers, more of what we commonly think of as *nature* – that part of reality that involves mind to some extent, but exists, and carries on by itself. On the one hand we are told that the nature of reality is the nature of *enlightened mind*; but on the other hand, we are told that reality is *that which originates and evolves minds*, some of which happen to be in enlightened states.

Although we typically think of western culture in terms of scientific materialism, western philosophy has also been firmly steeped in idealist positions for more than 2500 years. Consider Plato’s *Allegory of the Cave* which describes a world where perceptions are mere shadows projected on the walls of a cave, and like prisoners who cannot break free of their chains and escape the cave, most of us never break free of illusion and escape into the light of reality. Here, in this light, we would discover the Pure Ideas and True Forms of a higher, more real, reality, that are accessible not through perception, but through enlightened Reason.

The modern enlightenment produced a philosophy of Reason that laid the foundations for scientific materialism. Ironically, however, this same philosophy, primarily based on the work of Kant, maintained a skeptical attitude toward perception. This attitude still afforded the mind and its faculties of reason, a *more direct route to reality* than the body and its faculties of perception. Kant built an impenetrable wall between *phenomena* which is given in and as our experience, and *noumena* which is what is really real. Ever since, *ontology* – the study of reality itself, and *epistemology* – the study of how we know reality, have bent fractured domains of philosophical inquiry. Kant argued that we can never actually perceive the real, we could only investigate it through various methods. This led to a kind of correspondence theory of reality in which certain tools of logic, mathematics and reasoning, when used according to certain rigorous methods, could be trusted to *map directly* onto the noumena. The best we could achieve would be an accurate *map* of reality. Science was understood to be the practice of continuously improving and updating the map. As a result, science would go on to undermine the common- sense perceptions of ordinary experience, while offering fantastic notions from relativity and quantum mechanics as ontologically real.

The post-modern critique completely debunked any lasting notion of naïve perception and replaced it by firmly establishing the social, cultural and linguistically *constructed* nature of experience. It highlighted the complex processes of social, cultural and linguistic *conditioning* that over-determine the outcome of perceptual experiences. Post-modern variations of Buddhist traditions highlighted the problematic self-reflective and self-referential properties of the ego, and its infinite regress into conceptual abstractions. The wall that Kant had built between experience and reality, was reinforced with self-confirming loops of social media to such an extent that problematized not only perception, but also of any hope of “authentic, unmediated *raw* experience.” In this world, there would never be the possibility of a “seeing the clouds for the first time” or “experiencing your first kiss” because all “first impressions” were always already mediated impressions, always already primed by the ubiquitous media and fashioned into existence first in the mind, and etched into lasting existence in inescapable memories (de Zengotita, 2008). It seemed that perceptual moments had become obsolete. Or had they?

Perfecting Perception

If perception proved not to be trustworthy *in the mind of philosophers* it would prove to be *more than trustworthy* in the bodies of extreme athletes who had trained to be able to give up thinking when it mattered most.

> *When he went to strap on his chute, he noticed the canopy was wet. It should have been the end of his plans. A wet chute is unevenly weighted. When deployed, parts will inflate, others will not. Potter, not thinking clearly, decided the water was evenly dispersed and wouldn't be a problem.*
>
> *And it wasn't a problem – at least not for the first five seconds of the jump. "When I leaped," he says, it was right into the zone. Immediately my senses started peaking. I was moving at ninety miles per hour but could see in credible detail – minute fissures in the rock, tiny patches of lichen, bat guano. At the six-second mark, roughly 500 feet from the ground Potter deployed his chute. It opened asymmetrically. The wet sections collapsed, the dry ones inflated. Instantly, with the air currents unevenly distributed, Potter started spinning. From above, his friends started shouting "Avoid the walls!" Important safety tip, except with his guidelines twisted, there was no way to steer.*

> *Then the miraculous intervened: the guidelines began to untwist. Potter seized the moment, yanking his toggles. He knew the better move was to reverse his direction-- which would have sent him backward and out into open space – but for reasons he still cannot fathom he turned left instead. He was now heading directly toward the cave wall. Worse, the moment he turned, his chute collapsed, draping itself completely over his head.*
>
> *But Potter's senses were peaking. In the fleeting instant before his vision vanished, he caught a glimpse of orange. "We were filing the jumps," he recounts, "so we'd hung a rope about 400 feet off the deck for the camera man. It was glowing orange. And that was what I saw: a flash of glowing orange."*
>
> *He reacted immediately, grabbing for the rope, catching it too. But there was no way to tighten his grip. Potter was less than 300 feet from the ground and closing in on terminal velocity. His hands were already burning from the friction. When he tried to clamp down on the rope, his flesh flayed, then instantly cauterized. The pain was unbelievable.*
>
> *… Potter did manage to stop himself for a moment – but couldn't hold it.*
>
> *Again he started plummeting. Again he clamped down. Again he managed to stop. Not a moment too soon. With the chute still covering his eyes, he had no way of knowing, but Potter had halted himself merely six feet above the ground.*
>
> *His friends shouted down "Just let go!"*
>
> *Potter landed in a heap on the cave floor. His hands were destroyed, other parts as well.*
> (Kotler 2014, pp. 51-52)

Dean Potter is one of the elite extreme athletes who are pushing human performance beyond all previous measures and expectations. Cliff jumping and wing suit flying may depend uopn technologies that open up new performance ventures, but in these situations, technology is not the limiting factor – human potential is. Within our human potential, we are pushing beyond not so much the limits of the body (that's where technology steps in to give us wings and reinforce our outer protective shell) – but we are experimenting with the upper limits of human consciousness. In particular, these upper limits are associated with intentional-motivational and attentional capacities. These capacities are associated with processes that follow discrete neuro- chemical pathways in the embodied brain-mind.

In addition to physical skill and endurance training, extreme sports require athletes to train their consciousness to access not only higher *degrees* of ordinary potential, but also *higher human potentials.* new potentials are essential to perform in these domains, where successful performance means surviving. Intentional states need to be *clean*, i.e. clear of emotional distractions. Attention needs to be sharp and fine-grained to relevant targets (that are usually moving and changing at the same time). Performance at this level requires keen sensory acuity (what Potter refers to as "his senses peaking") and enhanced proprioception – a more-than-ordinary awareness of the body's own position, orientation, and angular momentum in space operating at levels beyond the normal human capacity to deal with accelerated change.

There is something even more exceptional happening here that separates the elite athletes from the rest of the field: space-time dilating and the dissolution of the self-complex. In extreme cases, these athletes have the ability to dilate the experience of space and time. As time slows down, the action slows down, enabling them to perceive crucial details and process more options. As time slows down, space seems to expand, enabling them to see between fast moving objects and intervene between them.

In most cases, these elite athletes are accessing states of "flow" where the self-complex, the "I-me-mine" mind that ordinarily governs our action, is absent entirely, leaving them the feeling of self-less-ness, where the body knows what it is doing, but the mind has not been invited to the event.

These six key features of enhanced potential in extreme sports: clean intention, tuned attention, sensory acuity, enhanced proprioception, time-space dilation and self-less-ness, can only be attained by techniques specifically designed to take advantage of the neural plasticity of the *embodied body-mind-brain,* the *EBMB.*[4] These techniques first disrupt the habitual, default patterns of the human operating system, and then secondly, train them to handle novel action potentials. It turns out that these are exactly the kinds of disruptions to the EBMB that advanced meditation training (especially Zen practices) are designed to do.

The physics of baseball (Adair, 2002) prove that the fielder must start running *before* he hears the crack of the bat, and that when he catches the ball over his shoulder, it had been impossible for him to see it first. His EBMB was processing an enormous amount of information in order to deliver his glove to where the ball was headed, just at the right time. For this to happen, the EBMB must be *perfectly* aligned with *how the world really is.* The same extraordinary levels of performance characterized the career of quarterback Joe Montana. But Montana reports that the entire time he played football "unconsciously." There are coaches of trainers all over the world, training people how to perform better by "getting the self out of the way" (Gallwey, 2010). In these non-ordinary states of performance, the EBMB is more attuned to the world as it really is.

So what goes wrong with everyday ordinary perception? And why are we so concerned that we don't actually perceive the world *how it really is?*

> *In the summer of 1978 I was living in Berkeley California as a first-year graduate student. One night, two friends took me up to the observatory high up in the northern hills of the city. From there you could look out over the bay to the beautiful nightscape of San Francisco. When you get to the observatory, you park on one side of a pedestrian bridge and walk onto a huge terrace courtyard on the other side. The courtyard is surrounded by a 4'H stone wall. Because the way it is built, at night you don't realize you are several stories high. The short wall gives you the impression that you are standing on a courtyard at ground level. This turned out to be almost a tragic illusion that one night. We brought with us a frisbee and took up positions at the periphery of the courtyard, the three of us like points along an*

---

[4] The term EBMB represents the continuum of perception (or continuous flow of perceptual streams) from world (hence *embodied*) to the holistic perceptual processes of the *body-mind* to particularized functions localized in the *brain*. This continuum is bi-directional, with afferent streams running "upwards" from world to brain, and efferent stream flowing "downwards" from brain to mind-body, to world.

> *equilateral triangle. We lost ourselves in the warm and sweet scents of the Berkeley hills, the wafting breeze and the flow of the game.*
>
> *The last frisbee throw of the night got away from me. It soared above the short periphery wall into the complete darkness of night. There were no lights illuminating the distances below. Spontaneously I jumped over the wall like I had jumped over many stone walls that line the pastured fields all across my home state of Connecticut.*
>
> *The next sequences of events are clearly etched into my memory like years in a storyline. Yet they must have happened in less than 2 seconds:*
>
> *As I leapt, and while still on the rise of my jump, my ears tuned into a familiar set of sounds – the HVAC equipment that was running outside the main building, some 4 stories below. Instantly, this perception triggered up with some episodic memory in my mind – matching perfectly with the sounds of the HVAC that I heard for two years outside my 4th floor dorm room back in college. Somehow, all in an instant of time, my EBMB processed this information, realized I was not 4 feet but 4 stories above ground level, turned myself around, got hold of the outer edge of the wall, and pulled myself up, over and back onto the terrace floor.*
>
> *Stunned, my friends hadn't even time to move from their positions.*

Had perception both failed me and saved me at the same time? What part of my perception was sleeping when I jumped over the wall? What had awakened my perception of the actual reality? Notice I say “my ears heard” not “I heard” the sound of the HVAC below. When the EBMB “takes control” of the situation, in this case out of necessity, it is as if the first person subjective “I” gets brushed aside, and this third-person objective “organism” chooses how to act. This organism scans the environment and chooses the course of action in a nano-instant. Like a reflex, except that there is a whole lot more information loading up and matching up. One door of perception is closed – the intersubjective “I” who is playing frisbee, and the other door of perception is thrown wide open. The “I” discovers itself to have been separated from reality, distracted by the intersubjective and social themes that were playing out between friends. The organism always reaches toward reality, always responds as an act-uality, which is to “act in accordance with reality.”

When performing together, extreme athletes must learn how to emancipate perception from the social self, and stay with the organism, the EBMB. In other words, they are training themselves to enter into zones of peak performance, simultaneously. If time-space dilation is happening, it must be perfectly synchronized. If split second decisions must be made, they must activate in the body-minds of each of them at the same time. If each is a self-less organism, then they must entrain themselves to the same patterns and rhythms of action.

Steven Kotler (2014) talks about the new science of ultimate human performance as learning to hack flow states from both a body and a mind perspective, and by integrating both psychological and neuroscientific approaches. Flow states are associated with neurochemical systems that function as performance enhancers as well as mood-boosters. The neurotransmitters most involved are *dopamine* which creates engagement and increases attention; *norepinephrine* which directs focus and locks attention on target, as well as increasing arousal without spiking emotional imbalance; *endorphins* which alleviate any potential pain signals and keep them from delaying action or reducing endurance; *anandamide*, which is a psychoactive chemical that elevates mood, amplifies lateral thinking, and inhibits fear response; and *serotonin* which enhances coping and endurance capacities. Kotler (2014) writes:

> These five chemicals are flow's mighty cocktail. *Alone, each packs a punch, together a wallop. Consider the chain of events that takes us from pattern recognition through future prediction. Norepinephrine tightens focus (data acquisition); dopamine jacks pattern recognition (data processing); anandamide accelerates lateral thinking (widens the database searched by the pattern recognition system)*. (p. 68)

As I mentioned above, this chain of events, unfolds in the *time-dilated* state of flow. "We" are allowed to witness, to observe intently, but not to interrupt or insert an agenda that is meaningful only in the context the intersubjective "I."

Josh Watizkin (2007) interprets the experience of time slowing down as the same as opening up the space in which we can act. Reflecting on a push- hands match he won to earn a world champion Tai-Chi title, Waitzkin writes:

> *Now think of me, Josh, competing against a less refined martial artist. Let's say I am in the process of instigating a throw that involves six technical steps. My opponent will experience an indecipherable flurry of action, while for me the six eternal steps of the throw are just the outer rim of a huge network of chunks. Our realities are different. I am "seeing" much more than he is seeing. (pp. 143-144) … The slightest variations in the way my opponent responds to my first push will lead to numerous options in the way I will trigger into the throw. My pull on his right wrist will involve twenty or thirty subtle details with which I will vary my action based on his nuanced micro-responses. As I sit back on the ground and trip his right foot, my perception of the moment might involve thirty or forty variations.* (p. 145-146)

These are, Waitzkin explains, the space-time dilation of flow states is a kind of sensory precision that is gained through intense focus on simple perceptual details.

> *Now my unconscious navigates a huge network of subtly programmed technical information, and my conscious mind is free to focus on certain essential details that, because of their simplicity, I can see with tremendous precision, as if the blink in my opponent's eyes takes many seconds.*

The key to this process is understanding that the conscious mind, for all its magnificence, can only take in and work with a certain limited amount of information in a unit of time – envision that capacity as one page on your computer screen If it is presented with a large amount of information, then the font will have to be very small in order to fit it all on the page. You will not be able to see the details of the letters. But if that same tool (the conscious mind) is used for a much smaller amount of information in the same amount of time, then we can see every detail of every letter. Now time feels slowed down. (p. 146)

> *It was the summer of 1977. I was a junior in college, working at Princeton University on a National Science Foundation grant for a lab that was researching the neurophysiology of learning. My role there was to prepare the research subjects – species Limax maximus – the common garden snail – by vivisecting the nervous system wholly intact from the body, and set micro- electrodes into key neural nuclei so the electrical patterns could be visualized on an oscilloscope. My instruments were tiny micro-fiber glass filaments attached to scalpel handles. I had to work with my arms secured by the wrists in stirrups to stabilize my movements. Precision required all work to be done under a microscope. The first day I watched as the microfiber blades hopelessly flailed under the microscope from the otherwise imperceptible trembling of my hands. This meant I had to give up all sugar and caffeine for the summer. Still, I found it impossible to work with required precision, and ruined specimen after specimen. I just couldn't imagine how I might make the precise, micro-level movements that were needed, with my macro-level hands and fingers. The coordinates just wouldn't compute. How could I have control over my hands at a level I couldn't perceive?*
>
> *Then one day I had an idea. I looked through the micro-scope and transported myself into the micro-world that existed there. I imagined my fingers to be telephone poles, and the spaces between my hands to be entire football fields. I drew imaginary yard-lines in between and envisioned how I and an entire team of football players could run around in between. In this imaginary world, the micro-fiber blades were the size of kitchen knives, and the specimens were the size of whole salmon. Still a difficult task to fillet out all the bones – but no longer an impossible one. In this virtual world the space to act had been opened, and with it came the slowing down of time. Each specimen prep took 4-6 hours of uninterrupted work, not unlike the demands placed on a surgeon facing a long procedure. Yet before I had a chance to be distracted by the thought "I wonder what time it is," the requisite hours had passed and the work was done. Soon I was depended upon to do all the specimen preparations for everyone in the lab.*

What is clear from these accounts, is that perception can be emancipated from the concerns of the social self, from the numerous distractions of the intersubjective "I"; from the compression of time and compaction of space, from worry and fear and rigid adherence to a single-minded ego-centric frame of reference, into a time-space dilation in which perception functions with speed, precision and efficacy. Furthermore, this emancipation is associated with the experience of being "in the zone" or in an extraordinarily pleasant state of "flow." We know that flow states depend upon discrete neurochemical pathways that rely mostly upon five neurochemical transmitters. These flow states are also related to experiences of time-space dilation brought on by demands for extreme perceptual acuity and achieved through intense focus, and/or the ability to tap into time-space dilation through imaginative exercises.

Perception by the Numbers

Some Definitions

Neuroscience has calculated the way information flows through our sensory organs and how that information is (or is not) exchanged with the brain and the conscious mind. In order to make sense of this, I want to precisely define "sensory organs," "brain," and "conscious mind." They are all functions within what we have previously termed the EBMB – the *embodied body-mind-brain.* We can say that the sensory organs are mainly "part of the body," while the terms "brain" and "conscious mind" refer to the *mind-brain* of the EBMB. The word "embodied" in EBMB seems redundant, but in this case *embodied* means *more than the body* as conventionally understood as built upon a skeletal frame and outlined by our skin. In this case *embodied* refers to an ongoing interaction with the world, of other sentient and non-sentient participants.

Embodiment is fundamentally *participation.*

The phrase "sensory organs" refers to the conventional ways we point to our eyes, ears, skin, tongue, nose, as the "instruments of perception" but includes more than them. The phrase "sensory organs" includes both the afferent and efferent electro-chemical neural networks through which information flows and is processed at specific sites along discrete pathways, through the body, to and from the brain and other organs such as the gut, heart, and lungs. The term "brain" here specifies those regions of the neural networks that are confined to the anatomical region of the brain – the organ in your skull. The brain has been extensively mapped into specialized regions, and its electrical activity has been extensively studied to give us a pretty good idea of the brain's unique roles in perception.

Finally, the term "conscious mind" refers to that part of perceptual information that we have conscious access to at any given time. It refers to the perceptual information that the subjective "I" perceives consciously. Consider, as an example, the Buddhist story of the man who mistakes a rope for a snake. Assuming his sensory organs and brain are normal, we would say that the sensory organs are perceiving the qualities of the rope, in the context of the light, angle, sounds, how much of the rope is exposed, etc. Some of this information reaches the conscious mind-brain, and some of it does not. *In addition,* the mind-brain is processing memories and thoughts, and incorporating imaginative "leaps" while attempting to integrate these into the sensory information to get a "full understanding" of the situation. Now remember, *embodiment* means participation. As all these elements of the embodied experience come together, some aspects will become *more conscious* to the "I" and some will be "deselected" from the conscious experience. The *conscious mind* that emerges, depends upon what information is selected and what is deselected. The conscious "I" therefore, ends up participating with an incomplete set of information. If the information that is "served up" to the "I" is heavily biased by memories of being bitten by a snake, or by warnings that primed the imagination to see a snake, then we would say the "mind" is participating with the idea of a snake, rather than the perception of a rope.

This notion of selection and deselection is a very important aspect of perceptual experience, and suggests something like an *evolutionary-adaptive fitness landscape.* As Jason Brown (2005) surmises: "Is speciation in the process of evolution analogous to specification in an act of cognition?" The point here is that not everything the sensory organs are participating with, *gets through to the conscious I.* In fact, *not much actually gets through!*

The fact is that every single second, millions of bits of information flood in through our senses. But our consciousness processes only perhaps forty bits a second – at most. Millions and millions of bits are condensed to a conscious experience that contains practically no information at all. Every single second, every one of us discards millions of bits in order to arrive at the special state known as consciousness. But in itself, consciousness has very little to do with information. Consciousness involves information that is not present; information that has disappeared along the way (Norretranders, 1991 pg. 125).

"The numbers are vast," writes Tor Norretranders (1991).

> The eye sends at least ten million bits to the brain every second. The skin sends a million bits a second, the ear one hundred thousand, our smell sensors a further one hundred thousand bits a second, our taste buds perhaps a thousand bits a second. … All in all, over eleven million bits a second from the world to our sensory mechanisms. We consciously perceive about forty bits a second – and that figure is probably exaggerated. (p. 126)[5]

"That is to say," Norretranders (1991) emphasizes, "only one millionth of what our eyes see, our ears hear, and our other senses inform us about appears in our consciousness."[6] The neuroscientist Jason Brown (2005, 2002,) says that this singular conscious perception, is a terminal outcome of a global *microgenetic process* which follows a branching, evolutionary-tree-like pattern. This microgenetic process includes several pre-conscious stages that progressively unfold the perception of a space-time world of objects. His microgenetic process model includes the sensory organs, but does not begin there. According to his theory of microgenesis, experience begins in deeper regions of primordial awareness associated with the neuro-affective pathways of the EBMB. In a previous article (Roy 2015) I have also described the microgeney of perception as a tree-like architecture:

> Perceptions, although primed by affect, are not guided by them. Rather, perceptions are guided by what we might call the 'appetitive drive of the senses.' The senses are not passive organs that function like windows opened up onto the world. The senses are more like open roads – they are designed to go somewhere. This is something that Goethe knew – our senses are not passive receptors but they are dynamic and creative actors that enact perception. The sequence from affect to perception, from feeling into the world to reaching toward the world is a process called 'perceptogenesis.'
>
> It is a process that can be described as having a tree-like architecture, where the roots represent the affect channels, which are immersed in and draw from the given-ness of the world, and the branches that reach toward the sky are the sensory organs. The affect channels provide the energy, the intentional-motivational state that vitalizes both the penetration into the world through the sympathetic drives of feeling, and the thrust out toward the world through the appetitive drive of the senses. The two movements prescribe an arc of transformation, where affect and perception objectify as image in the mind of a self. (p. 52)

The image of a tree helps us understand the way the sensory apparatus "sculpts" information content into sizable "chunks" for the conscious mind. "The primary activity of mind is to chunk experience into public and private events," writes Jason Brown (2005); where we would substitute his term mind with "body-brain" and the notion of public and private events to conscious mind and unconscious process. "The price of this chunking," Brown (2005) goes on to say, "is a loss of relations and a delimitation and focality of the events of interest." We are hard-wired at birth for perceptual processes to sculpt information in ways that evolved for us as a species. Microgenetic theory (Brown 2002) adds to this notion of sculpting, a sense of evolutionary "survival" of the perceptual objects that make it through to conscious mind, by surviving the sculpting processes of progressive specification (speciation) of the perceptual objects. For this Brown (2002) requires making the distinction between *sensation* – which is an earlier stage in the microgenetic process, and *perception* which is the final stage that is actualized in the conscious mind.

---

[5] Norretranders suspects the correct figure to be between 16 and 40 bps.

[6] Norretranders later says the more correct figure is 16 bits a second.

> Sensation enters into the microgeny at successive points. … a deep preobject is gradually sculpted by sensation to a final object. … The object is what survives a transit through this sequence. It is whatever happens to actualize. Depending on the moment in the object structure that predominates, one has a dream, an image, or an object perception. (Brown 2002, p. 8)

People tapping into states of peak performance, have learned to make these unconscious processes *conscious* so they can be tuned to different advantages. It is possible to train the EBMB to sculpt perfectly tuned patterns which embed an enormous amount of information relative to, let's say a game like chess, and packaged in the right sized "bits" for the conscious mind to access and bring to conscious perception on demand. The world Tai-Chi champion Josh Waitzkin introduced above, is also a world chess champion. He now heads an educational organization devoted to his "Art of Learning" program, where just this kind of "enhanced perceptual training" is being developed. "The clearest way to approach this [topic]," Waitzkin (2007) writes, is with the imagery of *chunking* and *carved neural pathways.*

> Chunking relates to the mind's ability to assimilate large amounts of information into a cluster that is bound together by certain patterns or principles particular to a given discipline. The initial studies on this topic were … performed on chess players who were considered to be the clearest example of sophisticated unconscious pattern integration. (p. 138)

Evolution has already given us a default setting on how our neural pathway are carved, limiting most of the perceptual information to unconscious processing, so as not to overwhelm the conscious mind. The next section explains the bio-neurology of these pathways, with their various gates of entry, as discrete regions whose functional anatomy have been shaped by evolution. It will detail from a neurophysiological perspective, why Brown's microgenesis model, Roy's tree metaphor, and Waitzkin's analogy are all correct: that the mind has "the ability to take lots of information, find a harmonizing/logically consistent strain, and put it together into one mental file that can be assessed as if it were a single piece of information." (Waitzkin 2007, p. 139)

While it is true that these neural pathways are *developmentally conditioned* during one's lifetime, they are *not developmentally fixed*. In other words, they can also be *developmentally repatterned.* Old pathways can be made flexible, and new pathways can be carved into new sensory flows that dramatically enhance the ultimate perceptual experience. *Understanding* this, we will find that it is possible to turn what looks like a deficit (the lack of information reaching conscious mind) to an asset (training and tuning the *more powerful* unconscious processes toward a conscious focus).

For now, we can translate these different ways of talking about the content of perception into the terms I am using in this paper, namely EBMB, sensory organs, body, brain and mind, in the following way:

The EBMB is a participant in the world actively engaging and exchanging millions of bits of information back in multiple directions. The body as a holistic organism, cognizes all this information in specific dynamic patterns that have evolved as the species evolves. The sensory organs are *active* participants in the world – they scan and probe, seek and hunt for those relationships in the world for which they have specifically been tuned by evolution. The sensory organs also participate with the brain through discrete neural pathways that lead to and from the brain. These neural pathways are not simple, open highways – they comprise a complex network of "gates" which select and deselect information, route and re-route the direction of information, and chunk information into manageable portions that can serve as conscious perceptions in the mind. This has the net effect of "sculpting" a conscious perception consisting of a tiny fraction of the global sensory information from world to the "I" of the mind. Note, however, that the "I" of the mind itself participates with more than just sensory information. The mind also participates with virtual information arising as thoughts and mental images, memories, fantasies and dreams. Virtual information is associated with different regions and different dynamics of the brain. The mind has to integrate sensory information with this virtual information. Yet something very important is still left out – the information that is "perceived and processed" by/in the body itself – the rich and complex proprioceptive operations, which by far outnumber all the other information flowing through the EBMB. The body itself is a perceptual organ, that "cognizes the lived experience into the background of all perceptual experience.

Part II: Background

The Phenomenology of the Background

Until recently, Western scientists and philosophers have missed the role the body plays in constituting the "background field" of perception. Typically, perception has been viewed as a cognitive function of the brain and mind. Studies were limited to the brain's neural processing of sensory information and the mind's conceptual framing of it.

When we think of the body, we usually think in terms of *sensations* rather than perceptions. We relate to bodily sensations as "feelings" – both physiological and emotional. We are able to make these feelings conscious, to hold them into awareness, without conceptualizing or naming them. In fact, the philosopher Eugene Gendlin (1962) has shown that the bodily felt-sense is *more precise* than language. There are many ways we try to describe our feelings beyond merely labelling them with a word. And although language often proves itself inadequate for this purpose, we usually don't become skeptical about whether we are really feeling a particular sensation. In other words, we can *foreground the bodily felt-sense in our consciousness without naming or conceptualizing it.*

The *percepts* of the body, on the other hand, are embedded in the deepest unconscious processes that are responsible for the most primordial levels of experience. These body-percepts are deeper even than the felt-sense, because they are the background information that enables us to locate the felt-sense *in our own body*. Only in rare, non-ordinary states do these percepts rise above the threshold of conscious experience, so it is more accurate to say they are processes of proto-experience. They are the processes of the "background." The proprio-percepts of the body enable us to experience the sense of the body as occupying space, as well as enable us to have the sense of space surrounding us in multiple dimensions. When the proprioceptive organs work along with the other senses, the body "cognizes" its own action in the world, making it possible, for example, for the outfielder to run to where the ball will fly, before they hear the crack of the bat; or for the batter to start their swing before the release of the ball, in order to have time to hit it.

Searching for the Background

> The deeper "layers" of the psyche lose their individual uniqueness as they retreat farther and farther into darkness. "Lower down," that is to say as they approach the autonomous functional systems, they become increasingly collective until they are universalized and extinguished in the body's materiality, i.e., in chemical substances. The body's carbon is simply carbon. Hence "at bottom" the psyche is simply "world."
>
> ~ C.G. Jung, "The Psychology of the Child Archetype" (1940), In CW, Vol. 9, Part I: The Archetypes and the Collective Unconscious, p. 291

Trying to "find" sub-threshold percepts is like the fish trying to find the water it swims in. On the one hand, it is everywhere, and pre-constitutes or is the precondition of being-in-the-world. On the other hand, it must, in some way, be also hidden in plain sight. For this reason, scholastics in the east and philosophers in the west and have been searching for "the phenomenon of the background" ever since the axial age (Bellah and Joas, 2012) when consciousness leaped into its modern, theoretic-rational structure. Prior to the axial age, humans were not capable of reflective consciousness – they could not use their minds to "turn around" to search inside their consciousness. When we did, we discovered divergent ways to think of the background – as something transcendent or as something transcendental.

In the east, the move was toward the transcendent—that the "background" that composed or pre- constituted human awareness, was a transcendent consciousness that existed independent of the material world. This consciousness (Big Mind, Brahman, storehouse consciousness) is often conceived as having different layers or levels of ever-more subtlety. These levels are often simplified to the terms gross, subtle and causal levels of consciousness. In the east, "searching for the background" is a *vertical and additive process* of awakening, in which we are trained to dis-embed our attention from gross or coarse appearances, and expanding one's personal awareness into more subtle levels of consciousness. It is a *vertical process* because the more subtle realms of awareness are construed to be accessed by "higher levels" of consciousness. It is an *additive process* because each higher level *transcends and enfold* the lower levels so as to be both higher and more inclusive (see Roy, 2014).

Following the enlightenment, western philosophers rejected mystical explanations of the background phenomena, and turned instead to meta-physical/ meta-cognitive explanations. This resulted in the positing of *transcendental* causes that were construed as *pre-given mental events* that were accessible to the human mind through laws of logic and reason. Like eastern transcendents, these transcedentals were outside the realm of phenomenal experience, which involves appearances and sensory perceptions. But unlike the eastern explanations, transcendentals were properties that existed *because of human minds* not beyond them.

Transcendentals existed *because human minds could reason through the phenomena to them.* These were the *noumena* that could never be experienced, because they were necessary pre-requirements or *apriori* in order for experience to happen. The Kantian transcendentals include logic and mathematics, and the apperception of space and time. Western enlightenment therefore was *vertical* but not *additive*—it required higher capacities of reasoning, to get at *deeper, more fundamental truths*, such as laws of logic and science. Science and the academic disciplines thereafter supplied the additive practices – augmenting the fundamental laws of nature with more and more empirical descriptions.

A third approach in searching for the background, is neither vertical nor additive. Rather it is pursued through deeper-descending and subtracting practices. Husserl's *introspection* for example, entailed a process of "bracketing" out the world (the subtracting phase) and tuning in to the primordial phenomenological apperceptions underlying conscious experience (the deeper-descending phase). Gallagher & Zahavy (2008) Varela & Shear (2002). Husserl was especially interested in the phenomenology of time consciousness. Husserl described three overlapping yet successive phases of consciousness: *protention-primal impression- retention.* Pro-tention is basically a pre-conscious orienting phase, of "pure intention" or "intention without an object" which overlaps and gives way to the primal impression of phenomenal objects, which in turn overlap and give way to a retention or subtle memory of the object. This last phase then giving way (and overlapping) the successive protention phase of the incoming "next moment."

By bracketing experience and focusing down onto a core component of consciousness, namely the presentational present, Husserl not only revealed the phenomenal nature of time-consciousness, but also excavated a new transcendental explanation of the background phenomenon as the "stream of experience" occasioned by the succession of intentional states.

Gallagher and Zahavi (2008) point out how Husserl's analysis of the structure of inner time-consciousness serves a double purpose for western phenomenologist in the tradition of introspection: "It is not only meant to explain how we can be aware of objects with temporal extension, but also how we can be aware of our own stream of experiences. (p. 88)

> There are thus two important aspects to this [Husserl's] retentional continuity. The first, the 'longitudinal intentionality' … provides for the intentional unification of consciousness itself, since retention is the retention of previous phases of consciousness. Second, since the prior phases of consciousness contain their respective primal impressions of the experienced object, the continuity of that experienced object is also established. (p. 88)

Husserl's *presentational time* serves as an *invariant structure that makes possible* the flow of consciousness as we experience it. They are structures not given in experience, but invariant structures that are independent and prior to experience. Unlike Kant's transcendentals, however, they do not exist on some metaphysical plane, but are structures of mental states associated with intention, and as such, can be made explicit as phenomenological processes in introspection.

Husserl’s temporal structure brought the notion of the background back from the noumenal to the phenomenal – that of the processural structures beneath experience. Still for the most part, this background was thought of as comprised of mental events. Husserl called these mental states “validities” (Dreyfus 2012) that “make up the ‘unnoticed,’ ‘concealed,’ *background* [emphasis mine].

Heidegger led the way for a new kind of *existential phenomenology* whose adherents rejected the idea that mental events, such as intentional states, could relate subjects to objects. (Dreyfus 2012) Instead, they said that all mental events, including intentional states, depended on a background that could never be made explicit, because the background was part of the phenomenon of world. Heidegger described this “world-bearing” aspect of being as “absorption.” “[His] existential phenomenology discloses the holistic, preconceptual, preintentional background into which we are already absorbed. Heidegger thought of the background “as an atmosphere” (i.e. like water to a fish) and as an atmosphere the background is precisely not the aggregate of mental states that Husserl from his detached phenomenological point of view mistakenly assumes.

It is in this sense of absorption, that the background *withdraws* from phenomenological examination, *in order to be the background*. The background is in a sense a “performance of the world” that enables the absorbed subject to pre-figure phenomenal objects in consciousness.

Over the course of the 20th century, “the notion of the background has progressively moved into the foreground of philosophical discussion” (Shusterman, 2012, p. 206).

> Over the past century, philosophers have increasingly recognized that the mental life of which we are conscious and through which we act to realize our intention cannot adequately function without relying on a background of which we are not properly conscious but which guides and structures our conscious thought and action. (Shusterman, 2012 p. 206)

It was generally agreed that the background would not only be *pre*-conceptual and *pre*-representational, but also *pre*-intentional. Over the course of few centuries, the background had “moved” in the imagination of scholastics and philosophers, both east and west, from the highest domains of the mystical and metaphysical, to the realm of the mental and intentional. Now it was generally agreed that the background was to be found elsewhere, *even further down* in proto-realms of experience.

A Theory of the Body

The theory of the body is already a theory of perception. ~ Merleau-Ponty

It was Merleau-Ponty (1964) who first claimed the primacy of perception as the ground of experience: “The *perceived world* is always the presupposed foundation of all rationality, all value and all existence” (p. 13).

> By these word, the “primacy of perception,” we mean that the experience of perception is our presence at the moment when things, truths, values are constituted for us; that perception

> is a nascent *logos*; that it teaches us, outside all dogmatism, the true conditions of objectivity itself. (p. 25)

Making perception primary, was and remains a radical philosophical position. It implies that perception is *prior* to experience and is pre-requisite to experience itself.

His claim runs straight against Kant's transcendental idealism and Husserl's transcendental intentionality. In fact, Merleau-Ponty argues that perception has been called into question, because whenever you make the transcendental the priority, you already have a contradiction of thought, that "turns perception into mere appearance." Although he accepts the Kantian doctrine that "all our experience of the world is through a tissue of concepts that lead to irreducible contradictions," he argues that the consequences of this even Kant failed to grasp. Here he echoed the American pragmatists, whom he alluded to as "the realist philosophers of America," who helped him distinguish between the "universe of perception" and its "intellectual reconstructions. As early as 1900 William James, writing about "The Abuse of Concepts," (James, 1977) in philosophical inquiry, rather casually implicates the perceptual order as the prior ground of experience: "

> The intellectual life of man consists almost wholly in his substitution of a conceptual order for the perceptual order in which his experience originally comes. (p. 234)
>
> "The great difference between percepts and concepts" James writes, "is that percepts are continuous and concepts are discrete." Concepts "make cuts" in the unbroken flow of perception, that are "purely ideal."
>
> If my reader can succeed in abstracting from all conceptual interpretation and lapse back into his immediate sensible life at this very moment, he will find it to be what someone has called a big blooming buzzing confusion, as free from contradiction in its 'much-at-onceness' as it is all alive and evidently there. (p. 233)

Note that James was already intuiting the "sculpting and carving" functions we talked about in previous sections. The contradictions of conceptual interpretation result from the "cutting up" of the ongoing-continuity of the perceptual processes. "Conceptual knowledge is forever inadequate to the fullness of reality to be known," writes James (1977). "Reality exists of existential particulars … and of existential particulars we become aware only in perceptual flux" (p. 245).

James warns us that concepts are secondary and inadequate that "falsify as well as omit, and make the [perceptual] flux impossible to understand." He explains why intellectual examination of perceptual experience creates the impression that perceptions are mere appearance, writing that "Conceptual treatment of perceptual reality makes it seem paradoxical and incomprehensible; and when radically and consistently carried out, it leads to the opinion that perceptual experience is not reality at all, but an appearance or illusion." (pp. 245-6). Why this is so, James summarizes in the following way:

> Briefly this is a consequence of two facts: First, that when we substitute concepts for percepts, we substitute their relations also. But since the relations of concepts are of static comparison only, it is impossible to substitute them for the dynamic relations with which the perceptual flux is filled. Secondly, the conceptual scheme, consisting as it does of

> discontinuous terms, can only cover the perceptual flux in spots and incompletely. The one is no full measure of the other, essential features of the flux escaping whenever we put concepts in its place. (p. 246)

A century later, Merleau-Ponty took this line of reasoning further, into the search for the “background phenomenon” by identifying “bodily space” as the “silent, structuring, concealed background. In his book *Phenomenology of Perception,* Merleau-Ponty (1962) attempts to redefine the “body” beyond its interoceptivity and proprioceptivity, and associated changes in the body’s posture and gestures and their associations with images and significance via a perceptual translation into visual and articulate language, which as such pinpointed the body as the center of classical perceptual experience. “And yet,” Merleau-Ponty writes, “the body schema clearly overflows this associationist definition.” (p. 101)

> Rather, these associations must be constantly submitted to a unique law, the spatiality of the body must descend from the whole to the parts, my left hand and its position must be implicated in an overall body *plan* and must have their origin there… (p. 101)

The emphasis here is away from body-as-schema and toward *spatiality* as *given* through the body. Remember, spatiality had been, for both Kant and Husserl, a transcendental category of experience. Merleau-Ponty is pointing to the body as the “perceptual organ of spatiality.” With latitude, we might say that the body “casts” spatiality, a field of continuous flux and flow which is simultaneously both body *and* world *in participation*. The body is expanded to mean, in a very real sense, an *emanation of the space of participation*.

The emphasis here is on perception as *direct participation* of the body’s spatiality, which is to say of *direct involvement* in a “field” of body-and-world. The emphasis is on its direct or unmediated nature, “that there is no intermediary (image or representation) between perceiver and object perceived.” This cuts strongly against the grain of classical, representational theories of perception:

> According to one classical formulation of this representational view, our mind cannot on its own reach all the way to the objects themselves, and the typical claim has therefore been that we need to introduce some kind of interface between the mind and the world if we are to understand and explain perception. Our cognitive access to the world must be mediated by some kind of mental representations relating to the everyday objects we ordinarily claim to perceive, as inner effects to external causes. [According to this view, then] to perceive the world is to generate a representational structure within the mind – something like a picture or map that represents external reality. (Gallagher & Zahavi, 2012 p. 101)

Merleau-Ponty opened up the possibility that the background is not the *pre*-perceptual ground, but the *perceptual-as-ground itself*. It suggests that there are perceptual processes that are pre-intentional, pre-representational, and pre-conceptual. These would mean that the background was the pre-intentional pre-representational, and pre-conceptual *perceptual processing of the world*.

> Bodily space can be distinguished from external space and it can envelope its parts rather than laying them out side by side because it is the darkness of the theatre required for the clarity of performance, the foundation of sleep or the vague reserve of power against which

> the gesture and its goal stand out, and the zone of non-being *in front of which* precise beings, figures, forms can appear. (Merleau-Ponty 1997, p. 102)

It would be a *participation* where world and body meet in the very fine-grained, finely attuned places where the distinction between “world” and “body” became too fuzzy to conceptualize. This field would be pre-ordered, open potentiality, where proto-perceptions emerge from the adaptive coupling of body and world, in active mutual participation.

“The world is experienced, not as a fully formed presence, but as a set of possibilities determined by an on-going dynamic interplay of environmental opportunities and sensorimotor abilities” (Gallagher & Zahavi, 2012 p. 111).

These proto-perceptions would then go onto different phases of “sculpting and carving” at different mind-brain “stations” along perceptual organ pathways, neural networks, and cognitive streams of consciousness. Some of this sculpting and carving would be done in primordial, pre-intentional stages, while some would be guided by intentional states and attentional needs, as well as eidetic phases involving memory and mental image-making while further cuts would be made through meaning-making processes of the social self. The whole gestalt would eventually, in imaginative and synthetic parts of the mind, be polished by symbolic, narrative, linguistic and conceptual elaborations of many kinds.

Neurodynamics of the Background

> *The body cognizes itself through its own body-consciousness, namely that of touch, which is "self-othering. The eye cannot see itself, the ear cannot hear itself, the tongue cannot taste itself, the scent organs cannot smell themselves. Neither can the self cognize itself; rather it is the outcome of a cognized moment. Only the body can cognize itself through its own body-consciousness, namely that of touch, which like one's own two hands embracing, is simultaneously self-othering. In this very same way, the body's aspect consciousness, its kinesthetic awareness, simultaneously self-others the world. This is the definition of unmediated cognition – the primary anchoring of perception in the world with and as the world, in participation*.
>
> ~ Bonnitta Roy

In this section I want to introduce the notion that the “body cognizes itself.” What I mean by this is that the perceptual processes associated with the EBMB create a holistic “knowing” of the body’s relation-in-the-world. This *tacit knowing* emerges through continuous participation with the world, down to finer and finer graininess where the boundary between body and world becomes “fuzzy” for the categorizing, conceptual mind. Consider for example, tasting food. The molecules of the food come into contact with my tongue. At this level of detail, the food is part of the world and the tongue is part of my body. At a finer level of detail, the molecules of the food come into contact with the molecules of my taste receptors. From there on, it’s all chemistry, which is the same “kind of chemistry” we find in the world. Chemistry is itself a participation at a fine level of detail.

The body "cognizes" by integrating three parallel-processing streams: *interoceptive,* and *proprioceptive,* and *exterioceptive.* These parallel streams are sub-systems that semi-independently integrate perceptual information (sight, sound, taste, smell, touch, kinaesthetic and vestibular organs) according to three different referents: 1) *Interoception* processes the body's position in space, mainly by referencing the head and its movements. 2) *Proprioception* cognizes the body's own position, mainly by referencing its center of balance. 3) *Exterioception* cognizes the body's position in the world, mainly through referencing relative positions of other objects. It's truly extraordinary how much information the body must work with simultaneously: processing six perceptual data streams through three parallel processes, into a holistically cognized tacit knowledge of its worldly participation. In this case, "to cognize" means to realize *itself as both body and world.* These are the processes of the "background" that Merleau-Ponty described.

This background is a holistic continuous inter-integration of body and world. It does not "appear" because it is not a thing, nor does it come to rest as a terminal point in a perceptual stream.

Rather, as background, "the body" performs a "cognizing purpose" through continuous participation at the rhizomatous interface of body and world. *The background is hylozoic*[7] *participation.*

James H. Austin (1999) describes the perceptual spaces of the body as "the normally hidden capacity for sensate inferences." It allows us to maneuver in 360 degree (i.e. circumspatial) space through a holistic integration of position, balance, movement, and enormous processing of incoming perceptual information. Unlike ordinary, conscious perception, which references experience to the body as a single point location and the world in front of our eyes – or even unlike inner mental images and thoughts that do the same – the body's perceptual space includes the ever-expanding and unfolding continuum of space in all directions. Hence, the athlete's space becomes an enlarged skill-filled volume of possibility. The outfielder runs in concert with the ball before the crack of the bat, negotiating body and ball through vast, circumspatial trajectories, just as we "know without thinking" to "reach without looking" behind us for our scissors or beneath us for our keys.

> In contrast, [to normal frontal-local perception] our hidden awareness is *un*conscious and *circum*spatial. It may seem to start out with that property which we refer to by calling it our ordinary "sense of place." But psychological tests suggest that our usual sense of place is already relatively large, and that it does not restrict itself to that limited zone which ordinary frontal vision perceives out in *front* of us. No, our true sense of *space* goes on to encompass a cycloramic field of no less than 360 degrees. Indeed, as our large visual brain goes on to represent this huge space, its scope extends *in back* to encompass a whole "visual world behind the head." (Austin 1999 pg. 488)

These background processes explain why, after higher level processing, we can parse the neurology of visio-spatial awareness into *egocentric* and *allocentric* frames of awareness. fMRI identifies these as discrete neural pathways through the temporal lobe, the one progressing upward in a dorsal stream, the other pursuing a downward course through a ventral stream. (Austin 1999).

---

[7] Hylozoism is a philosophical point of view in which matter is in some sense alive, or that matter and life are inseparable.

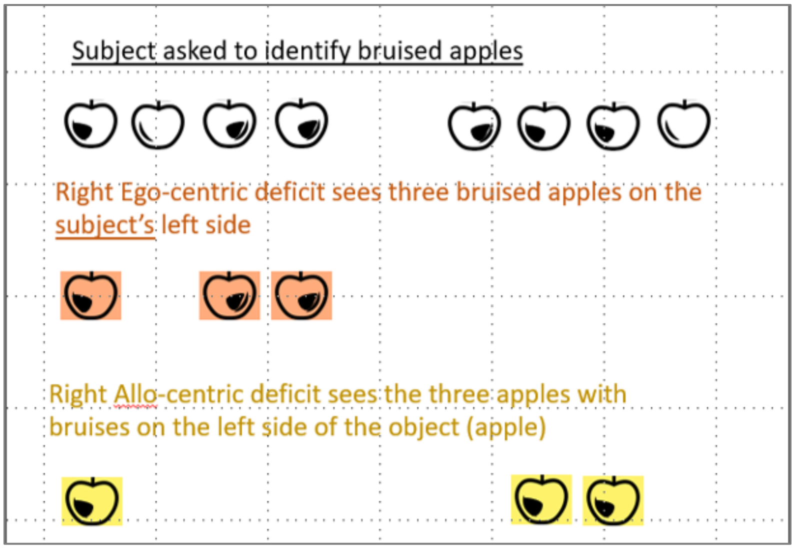
The egocentric mode references objects to points along the midline axis of our head and body. It takes the form of an object as it *appears to me, the viewer*. Its, purpose is design for action. It is hard-wired into our nervous system along with the dorsal-ventral body plan in utero:

> How did we develop this capacity to be aware, so unconsciously, of the spatial envelope around us? In utero, as yet unborn, our brain stem had no context for the richness of adult three-dimensional space, let alone for the extra dimensions it could reach during the alternate states of maturity. This tiny stem was still largely unconditioned. Yet the brain stem of a new-born baby is no table-rasa, no blank floppy disk on a computer. It is already channeling stimuli into certain designated regions. These will serve its primitive needs to localize. In this sense, the stem is a floppy disk already formatted. (Austin, 1999 p. 490)

Allocentric perceptual modes, by contrast, are more like GPS systems. They are tuned to detached, objective spatial information. This perspective develops later in children between the ages of 3 and 5 years. (Austin, 2009 p. 55). It is fundamentally world-referenced. It coordinates objects in the world in relation to *each other* and *their environment 'out there.'* The Allocentric mode takes the form of an object as 1) an independent entity, 2) with its own intrinsic center, 3) occupying a position in the environment relative to other objects, and 4) is independent of our presence. It is only in the unconscious levels of perceptual processing that these two modes operate independently, because by the time they are *once again further passed along and integrated into manageable chunks for the conscious I,* they have been integrated into a holistic baseline perception, in normal, ordinary awareness:

> Normally, this second, other-centered version will go on silently to join our first self-centerd frame of spatial reference in a merger as complementary as yin and yang. In this ongoing synaptic alchemy, a mosaic of interactions blends two parallel physiologies into a joint working partnership. (Austin, 2009 p. 57)

These two modes of perception are *normally* merged in conscious experience. But they can sometimes become unhinged, and therefore experimentally detected. Take for example an ingenious experiment designed to elicit selective deficits of egocentric or allocentric processing in patients with temporal damage to different temporal lobe areas. The experiment involved subjects looking at two groupings of (images of) apples – four on their left field of vision, and four on their right. Patients with parietal lesions associated with deficits in egocentric processing. failed to report the four apples, exclusively on one side or the other, depending on the side of the



Subject asked to identify bruised apples
Right Ego-centric deficit sees three bruised apples on the subject's left side
Right Allo-centric deficit sees the three apples with bruises on the left side of the object (apple)

Figure 1. Parietal lesion test.

parietal lobe damage. Patients with parietal lesions associated with deficits in allocentric processing were also shown apples in two groupings (left and right); but in this case six of the eight apples had a black “spoiled” marking either on *the apple’s* left or right side. There were three “left spoiled” marked apples, and three “right-spoiled” marked apples and two unmarked apples. The apple images were arranged in the following grouping

Patients with allocentric deficits identified only the apples with *markings* on the opposite side of the patient’s dysfunction, *regardless of the side of the visual field the apples themselves were placed.* These experiments confirm that the “hidden background” of spatial processing operates along two discrete phenomenological streams of perception. For one of these streams the primary anchor of reference is the ego-body. For the other, the primary reference is distributed throughout “objective” relational space among the objects themselves. Along with the interoceptive, proprioceptive and exteroceptive cognizing functions, these two “streams of spatial reference) constitute the manifold of “bodily (world)-space” – the primordial, perceptual background of experience.

Neural Gates

> We look at much more than we "see." Each second, by gross estimates, somewhere between 10^7 and 10^11 bits of afferent information smite our various sensory end organs. To shelter us from this barrage, the normal brain engages in an enormous filtering operation. Only the rare stimulus, murmuring the right password, manages to pass through. As a result, consciousness finally registers and perceives only a mere sixteen to twenty bits of information each second. (Austin 1997 p. 278)

The neurodynamics of the EBMB are mind-boggling in their complexity. The holistic performance of the perceptual system depends on dynamics of feedback, feedforward, timing delays, excitatory and inhibitory responses, serial and parallel processing, and whole-part relationships. The key layers of this complex architecture are (from bottom up):

1. Hylozoic zone
    a. Level 1 – Participatory interface with world
2. Level 2 – Bodily Space (the background is “cognized” through a manifold serial processing system)
    a. interoception (primary purpose: well being
    b. proprioception (primary purpose: balance and skill
    c. exterioception (primary purpose: action)
3. Object-Space (referential processes of figure-grounding)
    a. Allocentric modes
    b. Egocentric modes
4. Mind-Space (deselection through serial processing)
    a. Carving and chunking through serial processing of information
5. I-me-mine Self Complex
    a. Accommodating and assimilating perceptual dynamics with virtual components of mind, i.e. memories, mental models, narratives, linguistic, conceptual and abstract thinking, imagination, dream and fantasy.

We can use a heuristic to illustrate the various levels as a simple illustration of these levels of consciousness. (see appendix A). In this heuristic, the world and the cognizing body start at the bottom, and more "refined" perceptual information moves toward the top, toward the final self-complex. The bottom sections comprise the "EB" of our "Embodied-Body-Mind-Brain" model. The top sector represents the "M" mind, and the pinnacle is the Self-structure, which includes more than just the EBMB. (We might say that, when we add the self, we are working with the EBMB-S) The "B" brain would be the hard-wiring that is diagramed in the illustration. The horizonal dashed lines represent where we would expect to find discrete "neural gates" which selectively allows certain information to pass "up" while confining most of the perceptual information to deeper levels. These "neural gates, would be the reason we have different layers of "accessibility" – from the pre-conscious (world) to the fully conscious self.[8] The deepest levels are completely unavailable to what we ordinarily think of as "consciousness" and yet they constitute the profound consciousness of the embodied body which "cognizes the hylozoic realm." Introspective practices can reveal the complex knot of thoughts, stories, memories, expectations and fears that constitute the subconscious layering of the Self-complex.

Contemplative practices and focusing-attention practices such as chess and Tai-Chi enable people like Josh Waitzkin to become consciously aware of the normally pre-attentive dimensions of mind. While we have seen that the allocentric and egocentric modes of perceptual processing were proved to be discrete by neuroanatomical and neuropathological experiments on patients in whom they stopped functioning holistically, it is possible, through advanced meditative practices, to tease them apart and to experience their subtle nuanced natures. It is also possible, in rare meditative states, to experience some of the deepest of the background processes, including the spatial dimensioning of reality that the body performs in the hylozoic zone.

Usually, though as consciousness descends deeper into the bodily domain, the threshold of consciousness is rarely breached, and the body "steps into the flow and performs in the zone" – as we see with extreme sports and exceptional athletes.

Background processes, not ordinarily available to conscious awareness, can become conscious perceptual experiences, when the "neural gates" reverse themselves. This "reversal" wherein the background processes come forward, entails the absence of ordinary perceptual features such as sense of self, a relatively "bland" external world of static objects, the body's positional orientation in object-space, and a normal sense of time duration. Every night we go through processes where the action along these neural gates changes. No longer are outside percepts allowed through. No longer are the body's percept allowed through. No longer is the information selected and integrated into a waking sense of I-me-mine. Instead, am explosion of virtual scenes are activated, including a dream-self and her imaginary worlds.

Opening the Gates of Perception

> *During a 13-day period of radical transformation, I didn't fall asleep at all. Instead, I would lie down and fall into deep relaxation. Soon I would witness my body going into sleep*

---

[8] This paper stops with the fully conscious, but pre-reflective self. The self-state system becomes extended through self-conscious, reflection, and then further toward social, collective and transpersonal states. These latter are outside the scope of this paper.

> *paralysis. I could "look for" my limbs, my head, my pelvis, but could not "find them" in any part of my awareness. As the feeling of the physical body disappeared, consciousness seemed free floating. Keeping my eyes open, I was immersed in deep blackness, which I could not determine was the darkness inside the room, or the blackness behind my eyes. Either way, the blackness was strange, because usually some faint light can be seen through the windows, or some virtual imagery is active behind one's eyes. By contrast, this was complete darkness, very still. This void eventually would become more and more spacious, and tiny little specks of "light particles" were flickering. I would say though, that only about 1 -2 percent of the area was occupied by these tiny particles – most of the "space" was a dark void.*
>
> *The greatest impression of this void is that it was 360 degree dimensional. And expanding into ever-increasing dimensional space. There were no objects that could be used as referents to this dimensionality. The impression of dimensionality was given by this "movement" of expansion into spherical space. My consciousness seemed to expand with it. It was as if I were a particle of light that I could not, of course see. A tiny speck of awareness flickering in a great sea of expanding void. Most of the experiences were affectively neutral. But one evening, this expansion into the infinite void was accompanied by an increasing feeling of bliss. Of freedom. The further my awareness expanded, the more bliss, the more freedom. "Going out to forever" became a subtle goal, a probable destination. Then the body called me back. I heard a very faint, child-like voice, way back down from "where I had come" calling me to re-occupy the physical body, so "she"(the body-child) would not die. I experienced this as profound spiritual choice – absolute freedom and bliss on the one side, and guaranteed suffering on the other. I realized the Bodhisattva commitment to embodiment, for the benefit of all sentience. And so, I returned. This was the 13th and final evening of my most radical transformative journey. I had come back "for good."*

My experience shows how the "background phenomenon" can be experienced as a non-ordinary state of consciousness. This was not a dream – as I had full waking consciousness, which included the ability to witness and record the progression of experiential events. The background phenomenon constitutes the "spatial dimension" we create in our dreams. This one evening, however I was not dreaming, and my sensory perceptions were "gated out" through the phases of deepening sleep. And yet, "I" remained awake to witness as the background phenomenon predominated my experience. This process is described as the "downward passage" (Bradford, 2008) "which follows an orderly sequence characterized by "loss of [perceptual]objects" as they "degrade in a predictable fashion," as aims dissolve and motoricity ceases through relaxation practices (associated, in my case with the on-coming of sleep paralysis).

> In pursuing the downward passage, the mystic is buffeted by feelings embodied previously in objects of desire, affection, and fear. Ideation likewise runs forward with increasing independence of conscious intention. Inner- speech may surface in conscious awareness as auditory hallucination. (p. 57)

The end-state of such "downward passages" is an outcome of what goes off-line, and what remains on-line. In many cases, described by Brown, the downward passage "opens the gates of eidetic and archetypal images to flood through, as temporary substitutes for lost objects.

> The many forms of imagery, dreams, memory and thought images, hallucinations and illusion, eidetic and afterimages are markers of successive phases in the object-development … dreams, hallucinations, and imaginal images, followed by memory and thought images; then illusions, eidetic and after-imagery and finally the physical objects whose veridical perception entails the conviction of their being real. (Bradford, 2008, p. 59)

Of course, what is meant by "lost objects" in this paper, is not merely a phase in a microgenetic process. In this paper "loss of objects" also refers to an interruption of the body's *participation in the hylozoic* zone, that result from sleep paralysis, and neural gating of perceptual information that occurs during sleep processes. In my case, there was at first absolutely *no eidetic* content, with only the background and a few tiny specks of light, which were most probably effects of baseline retinal activity—and only in the final stages followed by the auditory hallucination and a "return to the body." Similar states occur during normal sleep phases—processes that are highly dependent upon "neural gating" at reticular nuclei junctions in the thalamus. Austin (1999) describes the role of this neural gate in *desynchronized sleep* (D-sleep) which 'enables our brain (a) to reactivate itself during otherwise drugged stupor of slow-wave sleep, but (b) to accomplish this so gently that we're not sent all the way up to the waking state.

> During our waking hours, stimuli from the outside shape consciousness. But during D-sleep the field of awareness can turn inward.[9] Now it can pursue directions other than those dictated by new sensory stimuli entering from the outside. In many other respects, D-sleep and wakefulness seem to be "fundamentally equivalent brains states." (p. 316)

Traditional meditation rituals are designed to take advantage of key triggers associated with "the passage downward" to root, background experiences. (Austin 1999) These include sleep-wake cycles timed to circadian rhythms that are most likely to express D-sleep. Depending upon the "spiritual pedagogy and doctrine" that accompanies students throughout their training, these state experiences can be seen for what they actually are – revealing the innate background processes of human consciousness – or for what we wish or imagine them to be – astral, divine or transcendent phenomena. Nature-based traditions such as Zen (Japanese) and Chan (Chinese) Buddhism tend to select the former, while the theistic tendencies of the Indo-European cultures, tend to elevate these experiences to transpersonal and divine domains.

Zen *does,* however have a term for such events: *internal absorption.* It arises as a paradoxical result of being both *intensely awake* and *perceptually asleep*. Its main characteristic is *how much drops offline from experience* while the *sense of self remains strongly online.* (Contrast this to normal dream states where exterior sensations drop offline, but virtual perceptions – images, stories, entire dream worlds and a virtual self – come online; while the waking self is completely absent. In states of internal absorption

> The person's mental field lacks sensations of vision, hearing and touch. Something stops them from entering from outside the world. Absent too are the subtler proprioceptive sense arising from inside the physical self. All that remains is clear awareness expanded to the nth degree throughout a vacuum plenum. (Austin, 1999 p. 476)

---

[9] Where "turning inward" means 1) participation exits the hylozoic zone and 2) allocentric processes are interrupted.

(Re)Directed Perception

Most of the EBMB's consciousness-processing happens below the threshold of our conscious awareness. Perceptual information is directed along multiple subsystems that integrate multi-modal information in various ways to create discrete layers of awareness. In addition, what comes "online" and what remains "offline", changes through ordinary sleep-wake cycles each day. The background processes are ever-present and constitute some of the most subtle of meditative experiences. These experiences "reveal the water to the fish" as it were; in moments of profound insight about the nature of the hylozoic zone and the non-separation of self and world. Some of what we know about the background comes from patients who suffer unusual perceptual disorders. Consider for example, the phenomenon known as *Blindsight.* Ordinary sight involves *two* visual systems. The higher-order system (the "first system") is the one that crosses the threshold of conscious experience. It processes in the lateral geniculate regions of the visual cortex in the (B) brain. Here is where the data from the retina is translated into a high- resolution image of the object so that it can become a *conscious* visual percept in the (M) mind. The second visual system is gated below the threshold of (M) mind by the superior colliculus to pulvinar processing stations in the posterior parietal lobe of the (B) brain. This second system is the "background operating system" of the visual perceptual organ, but is not limited to sight.

Like other "background operations" it is an integrated polymodal processor, which *wholly unconsciously* "constructs an orderly visual envelope of space enlivened by our hearing, touch, and other sensory modalities. (Austin, 1999) How can it do all this?

> Because its single, so-called visual cells are not exclusively visual. Many of them also respond to the auditory *and* somatic sensory stimuli which enter from that very same region of space. They are *polymodal*, synesthetic. (pp. 242)

So, in the colliculus, hearing, feeling, and seeing come together. Through selective amplification and (de-selective) attenuation of vast amounts of stimuli, the system "promotes less to become more."

> Suppose its cells receive a single sensory stimulus, and they make only a relatively weak initial response. The colliculus then "turns up the gain." Its circuits amplify the interactions among incoming stimuli. The result is to *multiply*, not merely to add, the physiological impact from each successive stimulus. In this manner, collicular nerve cells boost their responses enormously. (p. 242)

In patients who suffer from *blindsight*, the first visual system is temporarily or permanently "off- line" leaving only the second, background system. For these patients, their visual system seems to work "intuitively" since the fact they can point to and correctly manipulate target objects *without consciously seeing them*, suggests that there is a deeper, intuitive intelligence at work.

Blindsight unveils the performance of the deeper, synesthetic visual system. In normal sighted persons, the perceptual information is "passed up" through a series of both hierarchical and horizontal processing. Complex negative (inhibitory) and positive (excitatory) feedback mechanisms sharpen, refine and complexify, through visual association processes, a sophisticated perception of the object. “Currently, thirty or more cortical regions function as visual association areas,” Austin (1999):

> When anatomists try to plot out their intricate interconnections, their diagrams resemble the map of the Tokyo subway system. Some areas function more as feature detectors, while others go on to process representations of images. Out of this mosaic emerges that grand perceptual synthesis we so casually take for granted: the miracle of vision. (p. 243)

Similarly, in special meditative cases and “happy” accidents, the egocentric spatial-referencing system may drop offline, leaving only the allocentric system operating in the background.

Apparently, this is what happened to Douglas Harding, when, as a young architect trekking in the Himalayas, he was struck with a peculiar absence of localized space. Instead, he experienced the global awareness of space-surround, “utterly free of me.” “I had lost a head and gained a world. Lighter than air, clearer than glass, altogether released from myself, I was nowhere around.” (Austin 1999).

Just how intricate, effective and *independent of I-consciousness* these background processes are is mind-boggling and ego-humbling. The Daoists have a term for it: Wu-Wei which means doing by not-doing. It is spontaneous effective action guided by *direct participation*.

> *One night, in the middle of my 13 days of radical transformation, I received a call from the person who took care of my horse at her barn. The horse, a big thoroughbred named Remington, had a history of very bad stomach ulcers, and seemed to be in so much pain that he might die. Since I was in a permanent state of awake witnessing, I drove to the farm in the middle of the night to be with him. I walked into his stall, and sat down on the floor. He thrashed about in pain for several minutes, then collapsed with his head upon my thigh. Normally, I would have been very emotional through this; but since I was in this altered state of witnessing, I was filled with a sense of charged clarity. It was not a calm state, but a state of intensified energy and awareness. It was as if his energy body suffused with mine, and expanded out into the universe. Only the body was perishing. His eyes rolled back into his head, and his tongue crawled out of his mouth and onto my thigh. There was nothing but intensified silence and a huge expansion of energy. He died. I did nothing. I was nothing more significant at that moment, then a simple prop to keep his head from falling into the manure. Then the energy aroused itself, and he stood up, gently as not to hurt me. He shook his head and got on with eating his hay. I returned to my truck. It was an early winter evening, a moonless night with a soft snow falling. I drove the unlighted curvy backroads to my home. I remember being mesmerized by the way the headlight illuminated the treeline of the country roads. Suddenly, I was transported into a space that seemed 3000 feet above the road, like when you are in an airplane, taking off or landing. My conscious self occupied the background space of expanded awareness, while my body-self continued to navigate the truck on the journey home. I remember wondering to myself “who is driving that truck?” I brought my “self” back down and into my body by intentionally “feeling for” the steering wheel. The first perceptual inputs were auditory – the sound of the tires and engine humming along the road. Then when I could feel my hands on the wheel, the entire scene recomposed itself.*

There are two exceptional things happening in this event: 1) the "location of the self" and 2) the independence of the action-oriented body. The sense of self comes to be located in the "expanding disembodied space" of the background phenomena, absent any perceptual information, while the body itself navigates perfectly, guided by sensory processing. From the view of the self, there is what is called in Zen, the experience of *internal absorption,* (Austin, 1999) which is characterized by

> (1) no spontaneous thought; (2) an intensified, fixed, internalized awareness; (3) an expansion of especially clear awareness into ambient space; 4) the disappearance of the bodily self; (5) a distinctive closing off of all sight and sound; (6) a deep, blissful serenity; and (7) a marked slowing or cessation of respiration. (p. 475)

What remains most amazing to me, is not so much this "apparently transcendent" experience, which can be ascribed to discrete changes taking place in the "neural gates" of the hippocampus labelled by neuroscientist as CA1 and CA3 cells (Austin, 1999).

> What would happen if a person stopped that stream of messages which normally flows from CA3 cells on to CA1 cells? As part of his theory, Mandell postulates that such a deficit of messages might cause the comparator functions of the hippocampus to fail. As a result, the theory goes on to propose that … a "transcendent" consciousness would arise. (p. 184)

Rather, what is *most* striking to me is that the EBMB carried on perfectly well "without me;" while "I" dallied about, happily discombobulated in ambient space!

Part III: Mind

The Perceptual Brain

So far, we have discussed the embodied, body, and mind components of the EBMB. The "embodied" aspect pertains to the hylozoic zone and the interparticipation of body and world; "body" pertains to the full spectrum of "bodily space": the exterioceptive, proprioceptive, and interoceptive perceptual organs, as well as the allocentric and egocentric orientations. "Mind" refers to the serial processes that create "chunking" of information, as well as the functions that integrate the virtual perceptions, associations and memory into the I-Me-Mine self-complex.

This section focuses on the "B" brain aspect of perception. We can think of "B" representing the "wiring diagram" of the illustrations in the Appendix. In other words, "B" represents the neurological relationships and anatomical structuration that are responsible for perception. The neurophysiology of perception is excruciatingly complex, and researchers feel they have just begun to identify some of the key dynamics and relationships. This paper addresses just a few aspects that are key to our understanding of the perceptual pathways from world to self. These pathways can be thought of as having "neural gates" that stratify information processing into deeper, polymodal subsystems that process a huge amount of information through parallel processes; and "higher" order systems that are themselves stratified across the three thresholds of consciousness—subconscious, conscious, and self-conscious.

From a neuro*anatomical* perspective, the stratification primarily occurs in two discrete regions: the deep mid-brain centers such as the thalamus, superior colliculus, and central gray, and 2) specific nucleated sites along the dorsal-ventral pathways of the temporal lobe. From a neuro*dynamic* perspective, electrochemical pulses, "neural firing dynamics" up to speeds of 350 times per second, are responsible for bursts that can last or as long as 1.5 seconds. (Austin, 1999) In certain regions, such as the reticular nucleus of the thalamus, when these bursts fire, they "close the gate" within the thalamus and block sensate messages from passing further up the perceptual brain. Typically, after a burst, there is a pause, which can last up to 3 or 4 seconds. This produces an overall effect of rhythmic, wave-like activity, that flows across key neuroanatomical features.

> The conventional belief is that the reticular nucleus does not actually… "slam" the sensory gate within the thalamus. Rather, it helps the brain generate complex, rhythmic oscillations. First, these shift in the direction of *hy*perpolarization. Next, they rebound toward greater degrees of *de*polarization, that tendency toward excitation which is its functional opposite. As these oscillations shimmer in thalamocortical circuits, their waves take the form of rhythmic spindle activity in the EEG. (Austin, 1999, p. 267-8)

Cycles of excitation and inhibition also operate in a top-down fashion, such that increased activity in the evolutionarily newer parts of the cerebral cortex, excites GABA cells downstream in the reticular nucleus, which in turn activates the inhibitory bursts that attenuate sensate processing up the perceptual brain. (Austin, 1999) In this way, higher-order attention processes in the mind can and do shunt away sensate information arising from the lower-order background.

These higher-order attentional processes, associated with manipulating concepts and other virtual objects in thought (such as planning seating arrangement for a wedding in your head) has long been known to create "absent minded-ness" with regards to perceptions in the concrete world. Fortunately, the background processes most often "catch ourselves" being oblivious of things like oncoming cars. We are beginning to understand how to hack these processes in reverse, by quieting the symbolic, representational, and incessant worrying activities in our prefrontal cortex, in order to slip into the stream of peak perception required of exceptional performance – a condition that is often termed "hypofrontality." Hypofrontality with heightened sensory awareness enables extreme athletes to achieve remarkable feats. However, due to the excitatory-inhibitory cycles of the nervous system, once the task is done, the sensory gates crash and close out all perceptual information. Absent both higher order processes *and* the sensory stream coming in from the sensory organs themselves, these athletes slip into deep unity-absorption states associated with the ambient, circumspatial "vacuum plenum" of the background. Whatever perceptual information is left – the vast expanse of space, the towering mountain, or a dying bird – everything, including the sense of self, collapses into it, creating an incomparable experience of one-ness.

Later on that fateful day of errors described earlier in this paper (Kotler, 2014).

> *When Dean Potter (see above) finally got that parachute off his head, he found himself sitting on the floor of the Cellar of Swallows. Above him, his friends were running around, trying to facilitate his rescue. He paid them little mind. His body was pretty destroyed – again he didn't notice. Instead, his focus was entirely on the ground beside him, where a small swift with a broken wing lay dying. Instinctively, Potter picked up the bird, cradling it in his*

> *shredded palms. The connection was immediate. As soon as their flesh touched, he felt a powerful psychic union, as if his consciousness had merged with the bird's consciousness. In that instant, they were no longer two wounded creatures: they had become one…*
>
> *Potter ended up in this place of unity-consciousness: "I know it's hard to believe," he's recorded saying, "but the experience was so powerful, the connection so true. I just sat there with that bird, holding it while it died. When it died, I died with it. And I don't mean that metaphorically, I mean I became that dying bird.* (p. 55)

From a phenomenological perspective, the stratified perceptual brain can be understood in several ways: 1) what sensate information is "online" and what is "offline"; 2) what threshold of consciousness has the information crossed; 3) what aspects of experience are *hyper*active, and which are *hypo*active; 4) what sensations are amplified, and which are attenuated; 5) what is foregrounded and what is backgrounded; 6) where (if any) is the inside-outside boundary and 7) which (if any) self-state arises.

Research that integrates neurology and phenomenological reports from meditators trained primarily in Zen traditions, suggests that when meditators sustain global awareness or maintain single-pointed concentration, they are training the perceptual brain in ways that uncouple the recurring cycles of the brain's neural gates into more highly flexible and variable configurations. From this standpoint, Zen meditation training can result in notable effects: 1) Allow for persistent attention through wake-dream-sleep phases; 2) lower the threshold for conscious awareness into deeper layers of perceptual streams; 3) flood the conscious mind with vastly more perceptual information; 4) open the background processes to perceptual experience by, for example, consciously toggling between egocentric and allocentric modalities, which would disrupt the interior-exterior boundary of experience; 4) merging with the open, spatial modality of the background processes; and 5) awakening to the (nondual experience) of participation in the hylozoic zone. These effects are considered desirable to the extent that they dampen symbolically-conditioned and ego-centered modes of perception and amplify allocentric modes. This expands both the range of awareness into more inclusive domains of compassion and care.

The Primacy of Participation

As you read this paper, take a moment to reflect on the question:

What are you participating with?

There is not a lot of perceptual information in the grayscale marks on the page – and yet they provide stimuli for all kinds of activities in your mind. The phonetic alphabets enable simple marks on the page to be modulated from exterior perceptual data (the markings) into interior, aural perceptions as speech inside your head. Speech in turn invites mental images, and associative memories and feelings that participate in chunking the information into packages of salient meaning. The message I am trying to convey is translated into meaning you are attempting to make. The meaning is always a variant of the message. Participation is *never* replication. It *always* creates emergent novelty.

The Zen notion of *direct perception* was never meant to suggest that we can see the world *as it is.* It is more correct to say that the awakened state sees *the perception for what it is.* Perception is a matter of *degrees of constraints* in an infinite field of participation. The first, obvious constraint, is our human species biology. A second constraint involves our individual physiology – whether the perceptual organs are fully developed and healthy; as well their degree of skill, i.e. degree of attunement, refinement and acuity. A third constraint is state-specific and concerns a person's thresholds for conscious awareness – our ability to be "aware of" if not "fully conscious of" for example, the saccadic movements of my eyes, the perspectival constraints of my language, or even the normally pre-attentive ground of perceptual experience. While it is not possible to break through the first two constraints, *direct perception* in the Zen sense of *Kensho-awareness*, deepens and expands awareness such that it lowers the threshold of consciousness, such that even the background composition enters into the perceptual experience. Still, amongst these rare experience that qualify as *Kensho*, there are different degrees of perceptual awareness. The full spectrum of the perceptual experience might not come into conscious awareness all at once. There are often initial phases of absorption in the spatial ground, followed by an intensely vivid, and polymodal synesthetic "surround sound" phase whose panoramic vistas may (or may not) be accompanied by a subtle egocentric reference.

Sensory Clarity

Over the last 10 years I have worked with many groups and individuals both in the context of cooperative inquiry. When groups come together for transformative practice, they go through stages wherein they dis-embed from the limited role of their social self, and move into deeper, more authentic engagement with each other. (See Roy, 2016). There is a key indicator that the group is shifting from inauthentic modes of relating to open, participatory complex processes of relating that are creative, insightful and generative of collective healing. The key is when individuals begin to fall into a state I call *sensory clarity*. They realize, *as if for the first time*, that there is just a group of people sitting in a room together. This realization comes after a tortuous experience where people debate, challenge, attack, disassociate, pontificate, politick for power, complain, agonize – a full spectrum of neurotic behaviors set into motion by the projections, fears, defenses, and narratives stored up in the false persona of the social self. Once all this is dropped, and only when all that is dropped, do the senses actually come "on line" and people see each other as they really are, perceive the "scene" as it really is, in its simple, ordinary concrete reality. The experience is both remarkable and humbling at the same time. Remarkable, because as the senses come online, the colors, textures, and scents become vivid and crisp; and the heightened sense of touch can activate the sexual libido (kundalini) of the body (lower chakra). It is humbling in its complete ordinariness: absent the incessant internal dialogue, social strategizing, and psychic warfare that we are always otherwise participating with, the simple fact of our ordinary humanity comes to the foreground of our perception.

Sensory clarity, I believe is the pre-requisite for authentic human relating. We have to get to square one before we can build a shared or collective understanding – what Martin Buber[10] called I-Thou -ness. Understanding perception therefore, becomes a matter of importance in the realm of human relationship. Too often we facilitate group process by mitigating emotion, whereas too little attention is spared for the senses. It all comes down to *What are you participating with?*

---

[10] http://teacherrenewal.wiki.westga.edu/file/view/I+and+Thou+1958.pdf

If sensory clarity is a marker of the possibility for relational depth, I began to wonder if activating and alivening perception could be a portal to *generating* relational depth and intimacy. Too often we associate intimacy with affective modes of being – with feelings and emotions. I began to think of the many ways people have always added color and jewelry to themselves as part of their courting behaviors – effectively making the perceptual experience more intense. I also began to think of the role of music and song, and the way that being in the rich perceptual environment of nature or a museum, makes a great first date! Not to mention the deeply sensory experience of two people touching. I began to think of perception as the *out-pouring energy* toward the object that is desired or loved; whereas affect was the *flooding-in* energy of relationship. I wrote (Roy, 2015) "perceptions are guided by what we might call the 'appetitive drive of the senses.'"

> The senses are not passive organs that function like windows opened up onto the world. The senses are more like *open roads* – they are designed to go somewhere. This is something that Goethe knew – our senses are not passive receptors but they are dynamic and creative actors that *enact perception*. (p. 52)
>
> *Equine Assisted Therapy*
>
> *For over 15 years I have partnered with my horses to create equine facilitated transformative practices for adults. For the first 10 years, the practices involved mostly working with affective dimensions of human experience.*
>
> *Horses are especially good at stripping away our monkey minds and social narratives and allowing us to drop into our bodily sensations. Most people go about their ordinary lives with something like "locked-in" syndrome – they are participating only with thoughts, mental models, narratives, expectations, associations, etc… in their mind. Over time, however, I noticed that people involved in certain spiritual communities who seemed to be able to quiet their monkey mind, were often less successful in engaging the horses beyond passive accompaniment. The horses wouldn't bond, follow, joke around, or engage.*
>
> *Eventually I discovered that there was another kind of locked-in syndrome in which the person is fully absorbed in their body, and incapable of experiencing the outer world. They were in a very real sense, perceptually dead. I actually had to train people to use their everyday senses – like their eyes and ears and hands – to experience the horse in a sensory way. This was a real shock to me, and it continues to boggle my mind today. No wonder people don't have any clarity around their experiences in the world! Can it be true that most of us are dissociated from our bodies and disengaged from the world? If so, we are only left with the coarse-grained linguistic categories with which to relate – leaving us misunderstood and isolated in the process.*

From Self to World

The perceptual organs are in direct participation with the world. But the ordinary, everyday self withdraws into a simulated world of virtual perceptions, memories and thoughts that create and maintain the I-me-mine complex. This is the "house that monkey builds" (Trungpa 1987), the illusory fantasy world of ignorance (Austin, 1998) that splits us off and trap us inside. This creates an existential condition I call "Locked-in Syndrome" and leads to the errors and confusions that call perception into question. We can think of "locked-in syndrome" as the ego's frame of reference. From this particular frame of reference, visual perception is deceptive, because it does not correct for refraction of light in water. However, if a person uses their body to throw a spear at a fish, the perceptual EBMB *as a holistic participation* **does** the "calculation" through adequate participation: experienced spear fishers throw with precision. Locked-in syndrome makes us think that vision operates like a camera, rather than understanding perception as a holistic participation with the world. Experiments in visual perception exacerbate the locked-in frame of reference, as subjects' heads are literally held in place in front of displays. As it turns out, saccadic eye movements, subtle movements of the head, and the body's proprioceptions of angular rotation, play essential roles in perceptual acumen. (Clark, 2011). When we are locked-into our monkey mind, mistaking the simulated world for the world that arises from direct participation, our science degrades into linguistic recursion. For example, we know that the color blue was distinguished as its own color much later in human history than the other primary colors. From the point-of-view of the ego, obsessed with the virtualized world of language and thought, the reason why must be because there was no word for the color – that the *word* invented the perception, rather than the other way around.

Recent research (https://www.dunnedwards.com/colors/specs/posts/the-history-and-science-behind-the-color-blue) suggests a more embodied reason—that colors become lexically distinguished when people develop distinct *uses* for them. Just think about how significant this explanation depends upon embodied participation. Whether the color "exists or does not exist" in the environment is not the question. The question becomes "whether there is adequate participation" for the color to emerge as a distinct perception. This brings us to the notion of correct perception as *adequate* participation; and perceptual errors as a consequence of *lack* of adequate participation. This solves the perennial parable of the snake that is mistaken for a rope.

As I have described (Roy, 2014) before:

> *Let's go back to the story of the rope that is mistaken for a snake. The senses perceive "what is." If all of the reality enters in as context, then the person will experience the rope as a rope. If, however, the context is limited to a memory of a snake that once bit a dog, then the person is most likely to experience the rope as a snake. When the villagers hear her story, even though their senses perceive the words directly, if the context is limited to this story, then their experience will be one of limited participation, and they too will mistake the rope for a snake.*

Adequate participation *perfects science* as it leads us to a "good" theory which "orients us toward a correct view," which is to say, away from the separate, privatized view of the ego complex, and toward a view with more degrees of freedom. The ideal view, therefore, would be one with the requisite degrees of freedom to perceive that slice of reality of interest.[9] Participation, therefore, is the way our own EBMB activity *enacts or brings forth new systemic wholes* (Varela, 1991) which in turn creates new potentials for participation. Furthermore, the notions of adequate participation, informs the enactive and embodied aspect of skillful action and ethical wisdom in the world (Varela, 1992).

Recent studies in enactive neuroscience (Clark 2016, 2011; Gallagher 2008, 2005; Gibson, 2015; Noe, 2004) stretch the focus of enactive participation further into the dimensions of the "body-mind" (the "EBM" in the EBMB). In these approaches, the BM itself doesn't sit inside the brain, the mind or the body, but is fully extensive with "world" through the body's gestures.

The complexity of our human activities, they reason, are such that they cannot possibly be encoded and stored representationally in our separate bodies. Rather the body "stores the activity codes" for the kinds of participation that will *retrieve* the relevant information or *compute* the relevant data. We all know how we learn to count using our fingers. Clark (2011) tells us that gesture goes far deeper than that. He shows how gestures alone, or motor acts in general, "somehow shifts or reduces aspects of the overall neural cognitive load" in an "organismically extended process of thought." Consider writing as an example. Clark's view suggests that it is not that the paper serves merely as a medium in which to store our thoughts, rather, the participation is a bi- directional and emergent one where "the paper provides a medium in which… via some kind of coupled neural-scribbling-reading-unfolding, we are enabled to explore ways of thinking that might otherwise be unavailable to us. (p. 126) Physical materials, as Vygotsky (1986) understood them to be, *are carriers of cognitive effects*. According to McNeill (2005), then, this implies "that the gesture, *the actual motion of the gesture itself,* is a dimension of thinking." (p. 98) Echoing McNiell, Clark (2011) writes: "Our free (i.e. spontaneous, nonconventional) gestures are not… merely expressions of or representations of our fully achieved inner thoughts, but are themselves "thinking in one of its many forms"[11] (p. 127).

Ordinarily, we think of painting as depicting an eidetic image in the mind of the artist. A theory of action in perception (Noe, 2004) considers painting to be a deictic act, wherein the artist is not depicting, but reaching and pointing through polymodal bodily actions, involving the hand, the head, the eyes and more. "Instead of plotting a course through an internal map, you act on what you look at, and you let the fact that what interests you is there in front of you place a guiding function." (p. 24)

> Seeing, on the enactive view, is like painting. … The painter looks to the world, then back to the canvas, then back to the world, then back to the canvas. Eye, head, canvas, paint, world are brought into play in the process of constructing the picture. Seeing, like painting, involves the temporally extended process of reaching out and probing the scene. (p. 223)

Andy Clark (2011) calls Noe's model of perception "SSM" – a strong sensory-motor model. SSM's extend perception into the world through the activity of the body. Clark identifies a possible model that push the EBMB even further with his Hypothesis of Extended Cognition (HEC). The HEC predicts that whenever and wherever possible, cognitive information is exported onto the physical world in ways that create “affordances” for continued skillful action. Writing down a note to pick up a friend on the way to work, and placing it on the seat of my car is one example. Perception and cognition thus become not a matter of perceiving and knowing a world, but of reaching toward and building a world of affordances through gestures.

---

[11] The astute reader will recognize this as a version of the law of requisite variety in cybernetics: see http://pespmc1.vub.ac.be/REQVAR.html

Neural correlates suggest that this “dual-stream” hypothesis is correct – i.e., that there is a perceptual system that is EBMB-based, and one that is further removed from the realm of direct sensorimotor engagement. (Clark, 2011) According to this research, the visual processing system has two streams – a ventral stream geared toward “enduring objects, explicit recognition, and semantic recall” associated with more eidetic types of perceptual cognition. This stream operates whenever real-world objects are unavailable for employing as external instruments of perception. When such real-world affordance are available, another, semi-autonomous dorsal stream, operates in the here and now, to guide motor action in the world, without the mediation of eidetic representation. Like so many other recent discoveries, these distinct streams were “teased apart” by studying patients with deficits in one but not the other visual processing stream (Clark, 2011).[12] The discovering of “dual-streaming” processors lead Clark to suggest a new hypothesis of embodied perception and cognition: HOC (Hypothesis of Organism-Centered Cognition) which states

> Human cognitive processing (sometimes) literally extends into the environment surrounding the organism. But the organism (and within the organism, the brain/CNS) remains the core and currently the most active element. Cognition is organism centered even when it is not organism bound. (p. 139)

Some of the hypothetical territory here depends on how far are we willing to go with our conceptual categories. Consider again, for example, how we maintain our balance (part of the proprioceptive functions). Inside the inner ear a grain of calcium rocks on a kind of “saddle” that is lined with tiny hairs that sense its movements. As the head moves relative to the center of the earth’s gravity, the tiny hairs perceive the movement and position of the calcium. Now imagine being in a row boat, with a saddle for a seat. In your imagination, place a smooth and rounded stone in that saddle, and think of how you could use it to keep your balance as you stand in the boat. What if you had a serious ear infection, and your internal balance system went offline?

Would you be willing to *extend the category of perceptual organ out of the EBMB and into the boat?* Switching to the notion of correct perception as *adequate participation*, resolves the problem in one fell swoop. Perception is not a static architecture bounded within a conceptual category of one’s choosing. It is an active operation involving organism and world, that both extends and contract, reaches and retracts, to optimize participation.

---

[12] Note, previously we described the ego-centric and allocentric pathways that correlated with the ventral and dorsal subsystems of bodily space, which is consistent with the ventral-dorsal properties of visual processing described by Clark.

The Role of the Imagination

In ordinary experience, the imagination is tightly woven into the fabric of perception at various layers. There is the imaginary part that is intentional – for example, when we allow ourselves to imagine faces and animals in the morphing shapes of clouds. There are pernicious types of imaginary components that lurk beneath our consciousness, such as when we overlay bias and prejudice in creating false memories in reporting on crimes and mishaps. Direct perception, in the purest sense, is perception *absent the participation of imagination*. We can also think of direct perception, as *degrees of awareness* of the role of the virtual and imaginary in our experience. The greater degree of awareness, the greater choice we have to intentionally add in or subtract out the components of experience that are extraneous to the objects of perception. The integration of awareness and intention, consciousness and choice, is spiritual wisdom.

Perception and imagination begin to interweave deep in the (ordinarily) preattentive, subthreshold levels of experience. Because of this, the early phenomenologists (Crowell 2001; Gallagher & Zahavi, 2008; Kockelmans 1967; Welton, 1999;) argued that the imaginal, eidetic properties could never be perceived, because the perceptual properties of experience were themselves, products of imaginal operations. Only recently has western neurophenomenology and neuroscience begun to unravel their relationships in deeper layers of the EBMB.

Consider, for example, how we ordinarily perceive "first person perspective." We look from "here" to "there." We are unaware of the perceptual processing deep in the EBMB which subtle image-mind the shape of your body into this "picture" of reality. If you watch *this video* of a squirrel running up a tree, you will have what I call "go-pro" perspective. Because the movements are unfamiliar, the "body" your imagination ordinarily supplies as the "background" doesn't match up with the perceptual experience. Of course, there is a little bit of both "go-pro" and "first person" perspective in your experience. The point is, meditative practices can train the mind to decouple the imaginal or eidetic component of perception from the experience, creating a more naïve, more direct perception. Thereafter, the imaginal functions of the virtual-simulation operations of the mind, could reconfigure themselves in a kind of retroactive fashion, and offer you an imaginal body to go along with the video experience. You would be able to *become squirrel*. It is precisely this kind of "shape-shifting" that fascinated the Daoists sages and Shamans, who noticed that energy conspires with form to create perceptual experience. (Angle, Hall and Ames 1998; 2009; Hansen, 1992; Kjellberg and Ivanhoe 1996; Mair, 1983).

This imputing of a subtle mental model of the body onto "first person perspective" has led philosophers and phenomenologists to assume that the imaginative aspect of experience must be *prior* to the bodily spatiality of the world, and hence must somehow "taint" or "indirect" this aspect of experience. This has led to the idea of "the body in the mind." (Brown 2002, 2005; Heron 1992, 1996). For Brown (2002), the affect-laden intentional states preconstitute the subjective ground of experience. His theory of microgenesis places the "image" stage as a prior and requisite stage for the "body" to appear, and as a result exists for the subject as an object among other objects in the world. In similar fashion, Heron (1992) describes the basic life-cycle of the ego as moving from emotion to imagery, then conception and finally action. "the imaginal mind [is] at work in perception … it is a shaping and moulding process; perceptual imagery is being *made* by the psyche…

> I am not aware of my imaginal mind busy with the generation of perceptual imagery whether through seeing or hearing or touching. I turn what is a continuous process, a transaction, into something out there that I am looking at. I am aware of the image, the product of the process, but not of the imaging itself. (p. 145)

While it is correct to say that first person perspective already includes eidetic elements, it is incorrect to conclude that perceptual experience begins at first person perspective. Gendlin (2009) was already aware of this distinction when writing about the *implicit understanding* in the body:

> The first person process is not a 'perspective' First person process has been widely misunderstood as being inside an externally-observed body. I have tried to show that first person process is bodily-implied environment interaction. Our conceptual systems are explications developed from within environmental interaction, and then tested in it. In the usual view there is an unbridgeable gap between first and third person 'perspectives'. But only the third person is a perspective, a view (the 'view from nowhere', the observed without the observer). The word 'perspective' assumes that the environment is something merely viewed, not interacted with and behaved in. First person process is not a perspective. If first person process is understood from first person process, we can explicate how it is bodily, implicitly conscious, far exceeding the objects of attention (of viewing), always an implicit understanding, needing no added observer. (p. 349)

Thompson (2005) uses the term "sensorimotor subjectivity" as the "zero point," the "null point of orientation," or absolute indexical "here" prior to subjective being in relation to which things appear perspectivally: "The lived body manifests itself in perceptual experience, not primarily as an intentional object but as an implicit and practical "I can" of movement and motor intentionality" (p. 249).

The question is not *whether we can* virtualize the body using internal images and representational simulations. Rather, the debate involves whether virtual imagery is necessary for perceptual experience to occur. A third option is to suppose that the virtualization of visual perception is necessary but not sufficient for conjuring up mental imagery; and that in order to do so, requires the facilitation of on-going sensorimotor processes. The distinction between body *schema* and body *image*, described by Gallagher (2005) can help us better understand these options. For Gallagher, the deeper proprioceptive layers of the body are responsible for maintaining a coherent *schema* that locates and coordinates body movements. Body *image* on the other hand, involves higher-order processes that rely on mental framing at or above thresholds of conscious attending. Gallagher compares patients who suffer from two dramatically different types of deficit in their body awareness. Personal neglect" resulting from brain injury, involves the loss of "ownership" over movements in parts of the body. Arms and hands may manipulate objects successfully (as in dressing or undressing oneself) but the person is not aware of the intention or the act. According to his terminology, in cases of neglect, the deficit involves the *imaging* functions of the EBMB. In very rare cases, the body fails to locate or coordinate itself *by itself* and instead *requires* the patient to continually reference their body image and attend to their body as object, in order to make any movement at all. In the first case of neglect, Gallagher argues, the body schema is intact, but parts of the virtual body are lost.

In the second case, the body schema is lost, and the body image operates as the compensatory function. In some instances, for example with a patient named Ian, needs to see not only the target object, but also his hand in order to successfully reach out for objects. In other instances, Ian relies on cognitive control under the guidance of virtual body imaging, to articulate basic movement such as walking. This results in movement that is less fluid than normal – movement which looks more like a result of robotic "decision-path" calculation, rather than organic, embodied activity. The kind of movement that people ordinarily make when learning a complex dance sequence for the first time. For Ian, "imagined movement," Gallagher says, "lowers the threshold for continuous action."

> In place of the missing body schema processes, we might say that Ian has substituted a virtual body schema – a set of cognitively driven motor processes. The virtual schema seem to function only within the framework of a body image that is consciously and continually maintained. If he is denied access to a visual awareness of his body's position in the perceptual field, or denied the ability to think about his body, then, without the framework of the body image, the virtual body schema ceases to function – it cannot stand on its own. (p. 53)

Ian's condition shows us that in normal experience "there is no phenomenal difference between motor space, proprioceptive space and perceptual space." Yet it also brings up a kind of chicken-and-egg question, as to which is more fundamental. Gallagher surmises that it is only because Ian's vestibular and proprioceptive functions of his *head and neck* remain intact, that the visual-imaginary mapping successfully links the body to action (p. 63). Further research is warranted to determine the minimum viable structures and relationships required for different sensorimotor functions and associated actions. In any case, Gallagher anticipates that what will be found is something like an "ecological circle" between afferent signals coming from the body schema pathways, and efferent signals relaying back from the body image network. This of course, is the same kind of "circle" responsible for neuropathies such as phantom limb (Doidge, 2007).

This notion of an ecological circle in the EBMB is useful in other ways (see Appendix C). We can think of the body schema as located in the hylozoic zone – the ecological overlay of the body and the world. We can think of the body image as the ecological overlay of the body and the virtual mind. In this way we can calibrate the continuity of world and image, body and mind.

States of Mind

The imagination plays a preeminent role in the emergence of non-ordinary states of consciousness. The notion of "ecological overlay" is helpful in understanding how perceptual experience organizes as different state experiences, without disrupting the continuity of the EBMB. Thompson (2015) identifies what he terms "altered embodiment" along this ecological spectrum. These experiences are associated with specific neural correlates that overlap with those that specify first-person and third-person perspectives. I have already described how even in conventional first-person perspective, there is a subtle imaginative overlay of some third- person perspectival content. It is not difficult, therefore, to think of how amplifying one or the other, or combining elements of both, would result in non-ordinary experiences of world spaces and body spaces, and the location of the self.

Normally, the perspective of the self includes 1) feeling of ownership of the body, 2) sense of agency over its actions, 3) being anchored to or located in the body and 4) referencing the world to the body and 5) referencing affects (emotional tones) to the self. Any and all of these can be amplified or attenuated in non-ordinary states of mind. (Thompson 2015) *Autoscopy* is a phenomenon wherein the person perceives their body from an outside, third-person perspective, *while otherwise fully awake.* “Fully awake” here means you are simultaneously perceiving yourself located inside your actual body, for which you assume ownership and agency; while *in addition*, you perceive a duplicate body which arises as object of a third-person perception which you neither “occupy” nor “move.” A slightly different phenomenon, where the sense of the “I” that owns and controls, and to whom the world appears, alternates back and forth between the first-person and third-person body image. For brief moments, the two perspectives can be combined, a state experience called “bi-location.”

> *As I walked down the rows of corn growing in the valley, my sense of relative size became fluid. As a grew smaller and smaller, the corn rose higher and higher, until it seemed like I was looking up at the sky from the bottom of a deep canyon. The sun caught me at my throat and split me in two—a tiny self at the bottom of that canyon, and an expansive self who was floating above in the sky, witnessing its disappearance into nothingness*.

“The world of out-of-body experiences,” concludes Thompson (2015) “seems to be the world of the imagination.”

> In my view, the impression of seeing things in an out-of-body experience is like the impression of seeing things in a dream; in both cases, what’s happening isn’t perception, but the mental simulation of perception. (p. 224)

Perhaps it is helpful to say that an OOBE, is a particular ecological overlay between the perceptual body and the imaginal mind. Perhaps it is too rigid to assert that a given experience is “one kind of experience” and not another. If experience is an ecology of participation, then states of mind should be expected to be fluid and transitory between a spectrum of varieties of experience. In other words, because of the deep continuity of world, body, and mind, *all* experiential states are inclusive of world, body and mind – all the time. The differences Thompson has been describing all involve the degree to which the body schema operates and the degree of the body-image(ined) overlays. We might say that the “overlay” can be transparent in ways that complement the body schema, or, as the overlay becomes more opaque, the image- minded, virtual bodies, conflict with and eventually displace the embodied body schema. Falling asleep is an ordinary phase transition in this process of attenuation of the body and amplification of the imaginal mind.

First our ordinary perceptions quiet down, and the body sensations cease. We lose contact with our senses, and control over our bodies. The imaginal mind creates the dream world out of the overlays of perception, perspective, memories, fantasies, and narrative scenes and stories. Like film clippings on the floor of the editing room, snippets of reality can be spliced apart and spliced together in an infinite number of ways. One of the best ways to explore what imaginal overlays are operating in the background of waking life, is to learn how to be lucidly aware of the dreams you make.

An Ecological Theory of Perception

Using this notion of overlay, we can extend the scope of continuity of experience beyond conventional waking states and into other states of mind, such as the dream and sleeping states, and also including the mind's dying process and excursions into non-ordinary states of consciousness. Perception is a kind of multi-layered ecology of participation, where figure and ground, agent and environment, content and context can filter themselves in or out. I am thinking of the slider tool in a photo imaging app, where the transparency of objects can be set from 0 to 100 percent. Similarly, the overlays of perception, operate in a continuously shifting modes of transparency, creating different reveals, revealing new worlds. It should be noted that these "transparency settings" are not reserved to visual objects, but involve what we are calling all the "perceptual overlays" that make our experience complex, dynamic, and richly textured.

In the Appendices C-H I try to illustrate this idea of an ecological overlay of perceptual experience. Appendix C illustrates where the hylozoic zone is created by the overlay of the world and the body. This composes what we have been describing as the bodily space or background, (Merleau Ponty 2012, 1964), body schema (Gallagher 2005), first person *process* (Gendlin 2009), and the zone of sensori-motoricity that Thompson (2007) refers to as the "null zone" or "zero point." The shorthand I have used in this paper is simply EB, *embodied body.* In contrast, the body image, (Gallagher 2005) participates in the overlay between the body and the virtual functions of the mind – what we commonly refer to as the imagination or liminal space, and what I have labelled as the BM, *body-mind.* Appendix F is a way to illustrate where the ecological overlay of the many *virtual bodies* described above by Thompson (2015) would appear and disappear, phasing in and out of transparency, moving back and forth between the realms of possibilities and actualities (Whitehead 1978). Perception "rescues from vagueness", wrote Whitehead (1978) and warned us of "reducing perceptions to consciousness of impressions on the mind."

Affordances

In our ecology of perception, we identify the hylozoic zone as the world-body overlay; and the body image as the overlay of body-mind. What I construe to be the overlay between world-mind? I call this overlay "brain" since "brain" is the physical, or worldly aspect of mind. More significantly, "brain" represents what has evolved through the world as *world.* This is the MB, *mind-brain* at the end of our EBMB (embodied-body-mind-brain). This is the region labelled "affordances" in Appendix E. It is the region where the world accommodates the brain *and* where the brain accommodates the world. Brain and world constitute a continuum, in the same way as body and world – through complex, dynamic processes of relating. This dynamic "structural coupling" (Thompson, 2007; Varela, Thompson and Rosch, 1991) of brain and world is the basis of the notion that the world offers up novel possibilities, or "affordances" (Gibson, 2015; Masciotra, 2007) for the world and brain to co-create novel ways to participate.

A good example of affordance is the how we invent new uses for old items, when we don't have the right tool to do the job. Objects, lying around in the world, "afford" possibilities that the mind doesn't always see, until it sees it in a new light. We scan the room and go through the drawers, "looking" to find something we are not sure what we are looking for – until we find it. Then, brain and object, mind and world become one in the action made to solve the functional problem. Objects take on new meaning, the world grows richer. A blade of grass becomes a reed in a whistle, a whistle becomes a straw, the straw a handle to hold a nail in a tight spot. Every object in nature *affords* some possibility in the mind of a person. Affordance is a result of tight evolutionary fit between the organism and environment, which allows the organism to "dynamically steer" in the direction of the "good;" which is a satisfaction of a "search drive" in an adaptive landscape. Perception, as an ecology of overlay, can be construed as a continual dialing in and out of available features "afforded by the world" until it satisfies the conditions for a needed or desired action. A convenient analogy would be tuning a radio to a station that satisfies a threshold of fidelity. The imagination may or may not play a significant role in the final configuration. Regardless, the continuum from world to mind, is never broken.

This is a dance of "dynamic co-emergence" (Thompson, 2007): "all that a subject perceives becomes his perceptual world and all that he does, his effector world" (p. 59) This way of talking about affordances is subtly biased toward the subjective or organismic pole. The complete set of couplings between world and mind, constitute what von Uexkűll Barbieri, 2008; Buchanan, 2008) called the *Umwelt,* or the world that is disclosed through participation of the organism and their world. The emphasis here is on the world-building or world-disclosing activities (Heidegger, 1962). We can think of two agents participating in an overlapping Umwelt, where worlds and minds collide. This extension of perception *extended as world,* is illustrated in Appendix E. The intimate connection between the natural objects and the perceptual organs of man, was something that Goethe (1988) recognized: "The human beings knows himself only insofar as he knows the world; he perceives the world only in himself, and himself only in the world. Every new object, clearly seen, opens up a new organ of perception in us."

Goethe is saying that every new connection extends the organs of perception further *as world*, and generates self-knowledge. This very closely parallels the notion that perception, when awakened, gives rise to insight-wisdom in the Buddhist tradition (see following section). This underscores the fact that the perceptual organs are not merely passive instruments or message bearers, but they are actively engaged in the creation of a significant environment." (Buchannan, 2008). Furthermore, the mind is not required to interpret meaning from this engagement, because the significance is entailed in the environment-organism coupling, which acts as a "storehouse of meaning" that is accessible through iterative process of probing and participation. Pick up an old baseball bat, and you will re-live the significance of the hit; slip on a baseball glove, and you will recapture the significance of the game. "The creation of the *Umwelt* occurs through the *interpretive work of the organism"* [emphasis mine], writes Buchanan (2008):

> the interpretive process remains a biological relation that occurs between an organism and its other, where neither is reducible to a cause-effect scenario. They both give and receive the sign of the others, and it is in the *convergence of these signs* that an interpretive process takes place. [emphasis mine] (p. 33)

Goethe wrote:	*If the eye were not sun-like It could never behold the sun*
to which von Uexkull replies	*If the sun were not eye-like It could not shine in any sky*

(Buchanan 2008, p. 33)

In other words, there is something about the sun that *affords seeing*. This is not a trivial statement. *That* the world *affords* significance points to its inexhaustible richness and generativity. This is the basis of how perception gathers the world-disclosing information that generates insight-wisdom.

Gibson's (2015) own ecological theory of visual perception describes in detail the key aspects of the animal-planetary overlay that generates perceptual information. These aspects are the invariant constants that have been present throughout the evolution of animal life. We might think of them as the *way that the planet has extended itself into animal life*. The fundamental affordances of animal life are (1) The Medium: water, earth or air; (2) The Substance: water, earth or air; (3) The Surfaces: where media meet and create an interface. Note, according to Gibson's taxonomy of affordances, water is a medium for aquatic animals, but a substance for land dwellers (whose medium is air). The *affordances* of the environment, are what it *offers, provides,* or *furnishes*, either for good or ill. Like vonUxekull's *Umwelt*, and Thompson and Varela's notion of structural coupling, *affordances,* for Gibson, imply the "complementarity of the animal and the environment." Gibson offers a radical hypothesis of perception, which says that *to perceive is to reveal what the world affords*. Its radical implication is that to perceive is already an act of evaluation and meaning-signifying. This would explain the deep purposiveness interwoven into the very fabric of existence. As I have noted elsewhere (Roy, 2006), our fundamental values are laid down in the very primary micro-stages of moment-to-moment awareness. She writes

> I look out over a springtime meadow, taking in all the colors and textures and aromas. My eye settles on a daisy – not just any daisy, but just this particular one. My mind relaxes in the joyful play of this daisy and I. These are inherently valuable existents which exteriorize for me over the duration of the cognitive moments. For the bee, bird, and butterfly, there are a set of different values… (p. 145)

Changing values changes the way we participate in perceiving the world. This reveals different affordances. Think of the way we might scan though a bookshelf at a bookstore, without looking for something in particular. What catches our eye, depends upon some subtle ways our intentional-motivational state primes our behavior. We move along, picking up information—clues where to move next. We may be irritated in the self-help section, and get pleasantly lost in the biographies. A book of images, photographs or artwork draws our attention, and we move as our values move. We move, in a very real sense, guided by the appetitive drive of our senses. This is the same way that we move in and among the worldly significance. We interact with the world, and change it. Change affords new affordances, new significance, new ways of participating. "For all we know," writes Gibson, "there may be many offerings ... that have *not* been taken advantage of…" (p. 121)

To perceive directly, for Gibson, is to participate as the world affords. There is complementarity, but no intermediary. Take light, for an example. We ordinarily consider it a medium of transfer of information, between the world of objects and our perceptual organs. But, Gibson argues, we don't see light itself. Light in the environment is *ambient array*. It is an aspect of the medium (atmosphere or water, for land or aquatic animals) which, along with other aspects of the environment, i.e. substances and surfaces, interacts to create information. We in turn perceive this information *directly*. We see the green leaf because we receive this information: "the leaf is reflecting green and absorbing red." Perception is the *direct receipt of information in the* *environment*. As such it needs no interpretation. In a structureless environment, the ambient light itself would carry no information, and hence, *could not be seen*. Seeing is gathering information about the real world. It is direct participation with information that is structured in the environment. We not only perceive the world directly, but we *directly perceive the structure of phenomena*. This allows us to understand what they are and how they operate, a process McCabe (2014) calls *perceptual learning.* It is an intimate process, in which the world *enters us:*

> It adds that we resonate to and incorporate the information that specifies those phenomena directly into the neural networks that our perceptual systems activate. *This process changes us*… we are no longer our old self that has simply added another item to our archive of retrievable information. By incorporating new structural information directly into our appropriate neural network, we become a new, reorganized self… (p. 39)

The above discussion shows how a theory of affordances dissolves the crisp boundary between world and self, object and subject, in the same way that our theory of the hylozoic zone dissolved the sharp categories of world and body. Appendix G illustrates a third "fuzzy boundary" – the zone that overlays world and mind. We can think of this zone of extended mind, in terms of what Masciotra (2007) calls the *network of virtual actions* and *spielraum* (room to maneuver). The mind, in this case, constitutes the network of virtual actions; and the world of affordances constitutes the *spielraum*. We often think of creative insight as an activity of mind. The mind's virtuality and ability to simulate novel experiences, is only one key component of creativity. It might be secondary to how we participate with, and what affordances are provided by, the environment. "It is easier to enhance creativity by changing conditions in the environment than by trying to make people think more creatively" (Csikszentmihalyi, 1996, p. 1).

The *spielraum* represents the conditions in the environment that set both the constraints on and possibilities for creative excavation of affordances that have not been previously seen. This is perception as insight – bringing into reveal, the structures of the world, such that they align with creative ways of acting. A *spielraum* is not constituted merely by the objects in the environment, but by the objects as they relate to actions the body is capable of performing. Consider, for example, two climbers facing a rock wall. Their perceptual organs "see" the same wall; but the more experienced climber will see more "holds" for climbing. The more experienced climber will be able to virtualize more possibilities for a route up the wall, and then exercise these possibilities in real actions. For the expert, there are more affordances in their spielraum, including more potentials through which they can search in the virtual possibility space. The expert can translate these potentials into training exercises for the amateur, which will then, above a certain threshold of experience, become part of their real-world-actionable spielraum.

All agency is born of this suitable fit between the network of virtual potentials in the mind of the actor, and the set of affordances provided in the space in which the actor maneuvers. We might say that, in this zone where the mind and the perceptual world overlap, the mind provides the possibility space, the perceptual organs provide the search engine, and the world supplies the affordances.

Where then, might we ask, is perceptual information stored? Is it in the virtual simulations of the mind? In the perceptual pathways of the EBMB, or in the world? From the enactive view described here, the information is not stored any *where* but it is stored in the *number of possible functional relations between mind, perceptual body, and world.* In this sense, information is more of a result of being able to anticipate and respond; to be able to *search and retrieve* affordances as needed, then the ability to store some *thing* some *where* and subsequently to access *it from there.* Rather, what Clark is describing is an active, in-the-present-moment, dynamic, living participation. This is the sense in which Any Clark (2011, 2016) alludes to when talking about cognitive extension and "supersizing the mind." Here intelligence is thought of as the ability to organize virtual networks, with affordances in the world that are always "ready at hand" (Heidegger, 1962).

Perceptual acuity, (direct perception, adequate participation) reveals what is "ready at hand." Clark see this as an economy of embodiment, such that whenever and wherever it is possible to export the cognitive load of information/retrieval/storage tasks *into the world,* organisms will always choose to do so. According to his hypothesis, the organism retains the sensorimotor action-patterns that will generate successful search and retrieve processes in response to anticipatory processes set in motion by perceptual flows and intentional states. His three threads and two hypotheses are significant enough to quote in their entirety, so I have included them in Appendix I. They explain why the storage, processing, and transformation of information is spread indiscriminately among the brain, body and world – hence the idea of an ecology of overlapping perceptual zones which self-organize the continuity of living body and dynamic world. Clark proposes a *Principle of Ecological Assembly* which states that "information-processing organizations are repeatedly soft assembled from a motley crew of neural, bodily and external resources" (p. 197).

Enhanced Perception

So far, I presented an overarching model of perception as an overlapping ecology of mind, world, and body. I named the *hylozoic zone* where world and body overlapped; *body image* where body and mind overlapped; and *affordances* where mind and world overlap. In addition, I discussed that each of these overlaps could be extended further, to explain phenomena such as virtual bodies, extended mind and enhanced perception. Appendix H illustrates the zone of enhanced perception, which is an extension of the hylozoic zone in the overlay of world and body. This extended overlay represents what perception might be like if the sub-threshold information came into vivid awareness. In Zen Buddhism the experience is called *kensho* and it considered to be the confirming experience of direct perception. The following four excerpts are first person accounts of this type of enhanced perceptual experience.

Peter Matthiessen *The Snow Leopard*

(In this short excerpt, Matthiessen gives us a sense of the preparatory space of kensho, which beings with a sense of reorganization, recognition, and the clearing away of mental and emotional obstructions.)

> *The search may begin with a restless feeling, as if one were being watched. One turns in all directions and sees nothing. Yet one senses that there is a source for this deep restlessness; and the path that leads there is not a path to a strange place, but the path home. . . The*

> *journey is hard, for the secret place where we have always been is overgrown with thorns and thickets of "ideas," of fears and defenses, prejudices and repressions.*
>
> ~ Peter Matthiessen

Scott Russell Sanders *Staying Firm*

(In this passage, Sanders describes what I call "sensory clarity" something that on the one hand is ordinary, but, due to its perceptual vividness, becomes a sacred engagement."

> *I have spied that secret place from time to time, usually as through a glass darkly, but now and again with blazing clarity. One time it glowed from a red carnation, incandescent in a florist's window. Once it shimmered in drifting pollen, once in a sky needled with ice. I have seen it wound in a scarf of dust around a whirling pony. I have seen it glinting from a pebble on the slate bed of a creek. I have slipped into that secret place while watching hawks, while staring down the throat of a lily, while brushing my wife's hair. The experience is not a glimpse of realms beyond, nor of becoming someone new, but of acknowledging, briefly and utterly, who I am.* ~ Scott Russell Sanders

Alfred Starrett, *Your Self, My Self & the Self of the Universe*

(In this longer excerpt, Starrett wonderfully describes the no-self/Universal self experience of kensho, and its profound allocentric qualities resulting in an intensely luminous "surround-around" spatiality of creation.)

> *In the year 1925 my family lived on a small farm in Danvers, Massachusetts. My father was chief engineer at the Salem Electric Light Company. He had neither the time nor the inclination to work the land, but the farm was a pleasant place for the children in the family – two older sisters and a younger brother besides myself. I was ten years old that summer and thoroughly enjoying my love affair with the world. One pleasant moonlit night I responded to the call of some inner urge for adventure by climbing out of my bedroom window to the roof of the porch just below. From there, as I knew from many past excursions, it was easy to cross over the top of a couple of intervening sheds and reach the edge of the roof of the big barn. Soon I was up on the ridgepole of that tall building and I sat down feeling that I was at the highest point in all creation. The old farmhouse and the outbuildings were at my back and before me stretched low rolling fields toward a distant stand of trees and then rising hills. The air was clear and still. Moonlight washed out most of the stars and illuminated the scene. Below me Grunt, our pet pig, was making snuffling noises in his pen. As I sat quietly there on the roof of the barn I began to notice a strange transformation coming over everything I could see. Things were becoming luminous before my eyes. They shone from within, flowing with light in a riot of colors that continuously increased in intensity. It was as if the grass of the fields, the brown fences, the red barn that belonged to our neighbor, the white walls and green roof of our own house when I turned to look back – as if they all were made of stained glass with sunlight shining through them. As this inner light grew brighter I noticed that it pulsed with a steady rhythm that appeared to me to be the beating of some gigantic heart, as if it were the life-throb of the Self of the World. The scene became a living, scintillating dance of glory – everything beautiful and everything*

> *just right in relation to everything else. The very darkness of the distant trees and hills became shining purple and blue. Then something more strange happened.*
>
> *While still retaining awareness as an individual, the sense of "me" at a fixed location in space and time expanded into less limited conscious perception. I can try to suggest what happened by saying there was a shift of identity from the self of an observer to all that was there to be observed. Instead of seeing that living light, I became the light. It was seeing without any specific person doing the seeing from any particular perspective. The whole circle of the horizon was before my eyes simultaneously. My personal life became universal life. The rhythm of the luminous pulse beat was the surging rhythm of my own vital processes which had become identical with inner shaping and sustaining power of all creation. I could feel directly the variant urges, strivings and relationships of the different forms of the one limitless life. I felt in a tree its love for the earth and air; the holding-on of fence posts; the grass reaching toward the light; all things gathered and held in the supporting embrace of earth. I was also sensitive to conflict among the various forms, where life struggled with life and one kind of existence was absorbed into another kind. But the opposing tensions were experienced as one hears dissonant chords in great music which add to the beauty as they are resolved in harmony. How long the experienced lasted I cannot say, but eventually the process reversed itself. My conscious awareness took up again the perspective of a particular location on the roof of the barn. The light of glory faded. My seeing became a natural human vision again and I had returned to the sensory limitations of a little 6 boy with an aching bottom from sitting for some unknown length of time on the ridgepole of the barn roof.*
>
> ~ Alfred Starrett

In the fall of 2004 I had a radical shift in consciousness. I had this profound insight that there were *no sources or sinks* – that Love was not something stored over there, that could be moved to where it was needed; or that I could give or receive love. Rather, *Love was the ground and dynamic source of all that is*. I realized how all my life I had been running around trying to redistribute Love – from the perceived sources, to the perceived sinks, from those that could give to those in need. This included myself (give love to helpless animals, protect vulnerable people, look for someone to love, and for someone to love me). It was a kind of transactional kind of love, underscored by a sense of scarcity. In one fell swoop this final, underlying structure of my being was shattered. I entered in the dynamic continuum of love, a living flowing, dynamic stream of cosmic consciousness. I was going to the post office to pick up the mail. Boom!

> *Everything grew crystal clear like something completely transparent, except with brilliant hues of color. A hundred thousand kinds of crystal light – indigo, crimson, gold, sapphire, verdant greens of all hues – shown with incredible vividness and brilliance, yet with the transparency of crystal. I could hear the "clank clank clank" of the flagpole being rung like a bell by the metal end of the rope, high up in the air and behind me. At the same time, I could hear the soft "swish swish swish" of the blades of grass, each distinctly, like a slow progression of brushes over an orchestra of cymbals. To my surprise the sound they made tasted sweet. I could feel the undulating clouds beneath me and the warm breath of the earth, rising up to kiss them. Every sense was heightened and expressed itself overall as a kind of surround-around spaciousness. I did not want to move, for it seemed that taking even a*

> *single small step would be an impossible brutish act in an otherwise perfectly resonate energy field. No such disruption happened, for a long long time. But soon the ordinary way of seeing things, redeemed themselves from this spell of grace, and I made it into the lobby where the post-office boxes were lined up. At first, I couldn't remember which box was the one to open – and it felt strange, like a small amnesia. Which box? Which box? I had lost the memory in my body that knew which box it was. Then I reasoned – for the first time – that the number "30" in the address "30 South Main Street" identified the number on the box. It was like a grand puzzle was finally solved! The mind is useful, after-all.*

Part IV: Awakened Perception

A Buddhist Examination

No paper on awakened perception would be complete without passing the test of a Buddhist examination of the notion of direct perception. The key question in this section is whether this model can withstand the scrutiny of a Buddhist examination of these topics. Does the model provide useful heuristics for disentangling the complex ways in which the traditions talk about them? If so, might there be a need for the model for a modern approach to consciousness studies based on integral phenomenology?

Of course, there are many different Buddhist schools, whose opinions, beliefs and scholastics differ significantly from each other, not unlike the many different ways that western neuroscientists, phenomenologists, cognitive scientists and psychologists hold different accounts of perception. In this paper I rely on Anne Klein's (1988) interpretation of the Gelukba Sautrantika system, considered to be the most advanced exegesis of the direct perception, its relationship to conceptual thought, and their complementarity. It is a version that offers ordinary people the very real possibility of non-dual self-knowledge—which is simultaneously knowledge of self and world, self as world, and world as self—and as such has much of the defining characteristics of the ecological overlay model. According to this tradition, the possibility for non-dual knowing is given by the interpenetrating mutuality of thought, perception, and world, which leads to liberating insight. Hence, the ecological overlap might be a model of this possibility of liberation through awakening perception.

The Gelukba's hold that conceptual thought can lead to direct perception and the non-conceptual realization of self-liberating insight. This possibility however depends on having a correct conceptual framework. There are several key tenets to the Gelukba's framework. The first tenet has to do with ultimate truths, which are non-conceptual and apprehended directly, and conventional truths, which rely on conceptual apprehension. The key characteristics of ultimate truths is that they apprehend what is called "specifically characterized, impermanent phenomena"; whereas conceptual truths apprehend "generally characterized phenomena."

William James (1977) also noticed this distinction between perceptual flux and flow, the "big blooming buzzing confusion," the "aboriginal sensible muchness" and the concept which "never varies" and "expresses eternal veritas." In the western mind, it was therefore the "staying power" of the concept, James noted, to "contrast the knowledge of universals and intelligibles as god- like, dignified, and honorable to the knower, with that of particulars and sensibles as something relatively base which more allies us with the beasts. Hence these conceptual, intelligible universals were associated with ultimate truths in the western mind. "… by all rationalist authors the ultimate reality is supposed to be static also, while perceptual life fairly boils over with activity and change" (p. 247).

In the three highest Buddhist systems, Sautrantika, Cittamatra, and Madhyamaka, the opposite position was established, where only the impermanent, non-conceptual and specifically characterized were considered as ultimate truths (Klein, 1998). In line with the Buddhist schools, James understood that that to be conceptually known, "our flowing life must be cut into discrete bits and pinned upon a fixed relational scheme." James understood the problem with intellectualism, is the need to pin something down, as a fixed, permanent thing, and the farther we push it down the path of conceptual definition, the farther and farther removed it is from perceptual experience, which is movement, flux, variety, change – in other words, *impermanence.*

But intellectualism quickly breaks down. When we try to exhaust motion by conceiving it as a summation of parts *ad infinitum*, we find only insufficiency, Although, when you have a continuum given, you can make cuts and dots in it *ad libitum*, enumerating the dots and cuts will not give you your continuum back. The rationalist mind admits this; but instead of seeing that the fault is with the concepts, it blames the perceptual flux. (p. 247)

The Buddhist schools, on the other hand, understood impermanence, motion, flux, and change as *the first noble truth*; and the direct ascertainment of subtle impermanence as a sign of the highest instance of direct perception. In the Gelukba's framework, impermanent things fully appear to direct perception, and permanent things are apprehended by conceptual thought. (Klein 1998) Furthermore, what makes the things apprehended by conceptual thought, *permanent*, is not that they themselves are lasting and eternal, as thoughts come and go just like everything else in the phenomenal continuum. What makes them "permanent" is their ability to affix a single, *unchanging* generalized category, onto phenomena that are otherwise always undergoing continuous change – regardless whether that change is observable or imperceptible. Consider, for example, the category "chair." The conceptual mind is happy to stick with this term, regardless of whether the chair has three legs or four, undergoes multiple replacement parts, is constructed ad hoc by a convenient stump on the side of the road, or is displayed as an image on a screen.

Despite these dramatic differences, the word *chair* remains the same. The instances of all the "chair" themselves is never *specified*, but only *generally* characterized.

In the Gelukba's view, conceptions are valuable because they are essential tools for overcoming ignorance. And yet, our primary ignorance results from not recognizing the generalizing, categorizing, static and reifying nature of conceptual thought. *This too can be directly perceived*, through non-conceptual meditative awareness of the thought processes. By which faculties does the EBMB perceive the nature of its own mind? By lowering the threshold of consciousness such that one can follow the cutting, carving, chunking processes of thinking. Through meditative training, accessing flow states, and "happy accidents" awareness is able to access the deeper body-world interfaces where impermanent perceptions flow. That path to where knowledge is liberated from ignorance, requires that the subtle impermanence of even the most fundamental things, is cognized in a non-conceptual way.

In the Gelukba system, each perceptual organ is understood to be its own consciousness – eye consciousness, ear consciousness, taste consciousness, etc. These are said to be hampered by their lack of ascertainment. The mind also has its own consciousness, which is said to be "hampered by a lack of specificity." Yet, according to the Sautrantika view, each type of consciousness – sensory and mental – are ultimate consciousnesses when *directly perceived*.

To perceive directly means to "engage with the entire collection of features," in other words, to be aware of the ecological field of participation, from world to thought and back again. In doing so, we see that conceptual thought is not the omega point of conscious arising. Rather it is just another node in a continuous network of flow.

A conceptual thought, which is an object of mental consciousness, takes on the *appearance of standing in for the whole*, but the individual who perceives the experiential flow knows otherwise. Each thought is an iota, a grain of sand in an endless desert, whose shape constantly shifts in the eternal winds. An ultimately valid knowledge would be simultaneous awareness of the grain (the perceptual data) the desert (the generalized whole), and the shifting winds (the process of cognizing whole experiences).

An ultimately valid object – whether it be a thing, a feeling, a thought, a concept – would therefore be defined as a "set of direct perceptions that satisfy a duration of mind." The duration of mind might remain below the threshold where the hylozoic zone emerges from the world, and as such remain simply, world. The duration of mind might extend all the way through the formative processes of the fully articulated, self-reflective I-me-mine. The duration of mind might extend into the spaces that overlay the ecological field of participation, constituting novel states of experience. This notion of duration, is complementary to the Gelukba's emphasis on the process nature of consciousness (Klein 1998).

> Conceptual thought and direct perception can operate simultaneously, but they are not established or initiated simultaneously with respect to the same object.
>
> In the first moment of seeing an impermanent object such as a tree, direct perception – the eye consciousness – is active' then there is a moment of mental direct perception, which cannot be noticed by ordinary persons. Following this, conceptuality begins to operate. Thus, in the first period there is only direct, clear perception by the eye consciousness; once conceptuality begins, it operates simultaneously with subsequent moments of direct perception. This means that while the eye consciousness, for example, is apprehending the specific characteristics of its object, the thought derived from that eye consciousness superimposes a meaning generality onto that object. (p. 130)

"By understanding the profound compatibility between thought and insight," writes Klein (1998) one can have confidence that what begins as a mere echo of sound in the mind can progress to actual direct experience." The model of perception as ecological overlay, is offered to echo this sound, and to help build confidence. Integral phenomenology, as a method of unpacking experience through the examination of everyday ordinary affective, perceptual and conceptual phenomena, is offered as a "good enough" starting point, since, as Klein tells us, the Gelukbas emphatically believed: “The starting point is precisely the ordinary type of conceptuality and direct perception one now has.”

Part V: Concluding Remarks

Perception is a key domain of experience, yet it is hardly ever the focus of contemporary awakening practices, which have emphasized the affective and virtual domains (usually prioritizing the former, and prejudicing the latter)[13]. In both the eastern traditions and western science and philosophy, the emphasis has been on calling perception into question. In the process we have de-realized the world, and pushed it forever out of our reach. The core theme of this paper is that perception, as direct participation is perfectly attuned to the world, because it is something that the world does, in mutual participation with us. Error, confusion, deception and bias all result from a lack of adequate participation. Fully realized, authentic participation results in the experience of enhanced, direct perception of the rich, abundant, vivid display of reality, and a keen insight into our place in this sacred world. There is a sense of re-enchantment with the world. The philosopher Roy Bhaskar (2002) hoped that this kind of re-enchantment would set humans on a new course toward helping each other flourish and helping the planet to thrive. Our ability to perceive the deep continuity of body and mind, world and body, and mind and world are key to this journey away from destruction and toward regenerative practices.

In this paper I have introduced the notion of perception as an ecological overlay and a simple set of heuristics to illustrate them. The illustrations enable us to point to “What are we participating with” for any perceptual experience in different states of consciousness. Here the notion of what is hyper-active and hypo-trophied, what parts of perceptual experience are amplified, and which are attenuated, what is online in consciousness and what is offline, what is part of the I-me-mine self complex and what remains subthreshold to self consciousness – and how all these phrases ultimately point to complex neural processing systems, comprised of parallel subsystems, function as “neural gates” through feedback-feedforward, excitatory and inhibitory-dis-inhibitory relationships in the body-brain. I have introduced the notion of the EBMB, the embodied-body-mind-brain and the organs of perception as a useful way of conceptualizing the complex interactive and overlapping dynamics of perceptual experience.

This term “EBMB” underscores the overlapping of the world and body, hence “embodied body”, the overlap of mind and brain, hence “body-mind”, and the overlap of the mind and the physical brain, hence “mind-brain.” The brain, being a physical organ, represents the physical world, and completes the ecological circle. The heuristic of ecological overlay enables us to use language that is more nuanced and reflects the subtle distinctions in perceptual experience, beyond the coarse categories “body,” “mind,” “world.” In this way we are better able to talk about new areas of interest: how affordances are situated in the world and are revealed through insight; the distinction between body schema and body image; the hylozoic zone and bodily space; the allocentric and egocentric systems in object-space; among others. Furthermore, I have shown how and where all these "hybrid dimensions" can be further extended into a larger and larger perceptual field. The heuristic gives us an easy way to map the kinds of phenomena that happen in these zones of extension, such as virtual bodies, extended mind and enhanced perception (*kensho*). These zones of extension can be helpful in mapping the territory of non-ordinary states of experience. An adequate theory of perception must accommodate all of them.

---

[13] Before writing this paper I had been exposed mostly to contemporary western spiritual communities who practiced a sort of “watered down Buddhism” with post-modern overtones. Recently I have been exposed to a handful of practioners who represent both modern approaches while adhering to traditional insight practices that focus on the core teachings around perception (sensations).

A "good" theory orients us toward the direction of a correct view, where direct perception arises with the experience of an adequate participation with reality. (Roy 2014) In this sense, we might consider the Gelukba Sautrantika system a "good" theory. Any new theory of awakened perception must pass its strict examination, and few western theories of perception have complied with its view. On the other hand, the Sautrantika system does not pass the test of our modern scientific understanding which continues to expand the field of our knowledge about perceptual participation. I hope that integral phenomenology, which integrates direct experience with a scientific curiosity, can help bridge these gaps.

Andy Clark's Theory of Ecological Assembly

The Three Threads

1. **Spreading the Load.** The body and brain, thanks to evolution and learning, are adept at spreading the load. Bodily morphology, development, action and biomechanics, as well as environmental structure and interventions, can reconfigure a wide variety of control and learning problems in ways that promote fluid and efficient problem solving and adaptive response.
2. **Self-Structuring of Information.** The presence of an active, self-controlled, sensing body allows an agent to create or elicit appropriate inputs, generating good data (for herself and for others) by actively conjuring flows of multimodal, correlated, time-locked stimulation.
3. **Supporting Extended Cognition.** The presence of an active, self-controlled, sensing body (a) provides a resource that can *itself* act as part of the problem-solving economy and (b) allows for the *co-opting* of bioexternal resources into extended but deeply integrated cognitive and computational routines.

Hypothesis of Cognitive Impartiality

Our problem-solving performances take shape according to some cost function or functions that, in the typical course of events, accord no special status or privilege to specific types of operation (motoric, perceptual, introspective) or modes of encoding (in the head or in the world).

Hypothesis of Motor Deference

Online problem solving will tend to defer to perceptuomotor modes of information access. That is, we will often rely on information retrieved from the world even when relevant information is also neutrally represented.

Late Stages of Adult Development: One Linear Sequence or Several Parallel Branches?

Thomas Jordan[1]

Introduction

This text is intended to serve as a starting point for a discussion about the nature of late forms of adult development. It is primarily of interest for readers who are familiar with one or several stage models, such as ego development stages and hierarchical complexity levels. The basic proposition (to be critically scrutinized) is that frameworks that describe adult development as a linear sequence of stages defined by one core variable (such as hierachical complexity or ego structures) do not accurately represent the diversity of the "higher" or "late" forms of adult development.

Most theorists of late stage adult development advocate one particular theoretical framework, such as Commons' Model of Hierarchical Development, Dawson's Lectical Assessment System, Cook-Greuter's elaboration of Loevinger's ego development theory, Kegan's orders of consciousness, Jaques' Complexity of Information Processing framework or O'Fallon's StAGES model. Ken Wilber (see e.g. Wilber, 1999) is a notable exception, using the notion of different lines of development and the distinction between structure-stages and states to build a very differentiated conceptual framework for understanding the nature of consciousness development. Otto Laske (2006, 2009) is another theorist who advocates the need to differentiate between different domains of development that might develop at different paces, such as socioemotional development (Kegan) and various aspects of cognitive development (Basseches, Bhaskar, Jaques and King & Kitchener).

Scholars focussing on the complexity aspect of adult development have generally ignored to consider the phenomenon of "spiritual awakening" or "enlightenment" as possibly relevant to understanding higher forms of adult development. Since this theme is probably quite foreign to many scholars in the adult development field, I will make an extra effort below to point to the potential insights that can be gained from considering empirical research on this phenomenon.

I hope to entice more adult development scholars with different theoretical orientations to consider what can be learnt when different frameworks are compared and contrasted against each other, thereby also challenging implicit or explicit assumptions that late stage adult development can be accurately understood in terms of a single line of development.

---

[1] **Thomas Jordan** is associate professor at the Department of Sociology and Work Science at the University of Gothenburg, Sweden. He shares his time between research on meaning-making regarding complex issues, teaching conflict management and adult development at the university and training organizational consultants and managers. SOME RIGHTS RESERVED

This paper has three main parts. The following section briefly discusses a number of key concepts that I feel are needed in order to have a differentiated discussion of the nature of late stage adult development. After that, I will present a number of tentative but somewhat incisive propositions to be critically reviewed and discussed. The last main part sketches 5 prototypical late stage profiles of individuals that cannot easily be assigned to different stages in a linear developmental stage framework.

Key Concepts

It is necessary to define terms in order to be able to meaningfully discuss the complexities of adult development and spiritual awakening. This is a bit tedious, but it is a precondition for developing more clarity. Actually, I believe we need quite a few key concepts that represent various aspects of development. Here is my selection.

High ***cognitive complexity*** refers to the demonstrated capacity of a person to form mental representations of complex relationships between concepts and to make use of concepts at high levels of abstraction in order to resolve complex tasks. Levels of cognitive complexity can be defined, described and measured by analytical frameworks like Michael Common's MHC (the Model of Hierarchical Complexity; Commons, 2008; Commons & Richards, 1984; Commons et al., 1998), Kurt Fischer's skill theory (Fischer, 1980; Fischer & Bidell, 2006), LAS (the Lectical Assessment System, based on Fischer's skill theory; Dawson & Gabrelian, 2003; Dawson & Wilson, 2004) and Elliott Jaques' CIP/CMP (Complexity of Information/Mental Processing; Jaques & Cason, 1994). MHC, for example, describes levels of hierarchical complexity, such as Concrete, Abstract, Formal, Systematical, Metasystematical, Paradigmatical and Crossparadigmatical. It should be pointed out that scholars operating with hierarchical complexity frameworks usually do not assume that individuals are "at" a particular stage. An individual's performance can vary depending on domain, degree of scaffolding and other variables. There are large similarities between the frameworks mentioned above, but also some significant differences. The main difference between MHC and LAS is that the latter framework refers to tiers, which are defined by the levels of abstraction of the objects people use when reasoning. A rather different framework for describing and analysing cognitive complexity is the typology of forms of dialectical thinking formulated by Michael Basseches (1984) and elaborated by Otto Laske (2009). This framework focusses post-formal reasoning using a typology of thought forms. The emphasis is not on stages/levels, but on the extent to which a subject considers factors relating to context, processes, relationships and transformation.

Complexity awareness refers to awareness of and expectation that there might be many varying conditions, causal relationships, system properties and other factors that influence a particular issue or task (Jordan, 2011; Jordan et al. 2013). Weak complexity awareness means that a person is simply not aware of the possibility that there might be significant complex conditions that impact a certain issue. Strong complexity awareness means that there is an expectation (or pre-understanding, German *Vorverständnis*) that there can be complex conditions, explanations and consequences related to, for example, a particular task. Strong complexity awareness does not necessarily imply a high level of individual capacity for forming very complex mental representations and solutions to complex tasks. Sometimes it means a recognition that it will be impossible for the individual to gain knowledge of and coordinate all factors and systemic interrelationships that need to be taken into consideration. The person will then engage in action with an awareness that knowledge is very incomplete and/or will be motivated to build networks of actors that can generate collective capacity to deal with complex issues by drawing on diverse competences and sets of knowledge.

Strong perspective awareness refers to metasystematical reasoning applied to recognizing, comparing and using complex systems of notions (such as concepts, problem formulations, assumptions of causal relations and values), i.e. perspectives (Jordan, 2011; Jordan et al. 2013).[2] A person with a strong perspective awareness is able to take his or her own interpretive system as an object of reflection, recognizing how the properties of the interpretative perspective one is using condition what awareness focusses, how issues are thought about and patterns of making judgments. This leads to a rather low propensity to identify exclusively with a particular perspective (e.g. an ideology, a belief system, a discourse) on the one hand, and interest in using the contributions of alternative perspectives for a richer understanding of issues on the other hand. People with a strong perspective awareness recognize the constructed nature of all systems of meaning-making and can, at least to some extent, recognize the partial nature of their own favoured perspective. Examples of this can be to admit that one's own perspective is ill equipped to perceive certain aspects of reality, has blind spots in terms of circumstances that are marginalized by way the perspective foregrounds particular ideas and relationships and makes use of a large set of concepts that inevitably conditions how reality can be represented.

The ***ego development*** frameworks (following Loevinger and Kegan respectively: Loevinger, Loevinger, 1976; Hy & Loevinger, 1996; Cook-Greuter, 2010; Kegan, 1994) describe how individuals develop through a sequence of more or less universal stages, from birth through childhood and adulthood. Ego development theory describes a person's ego as a structured whole that develops as an integrated system through a linear sequence of stages. Jane Loevinger's ego development framework was built through pattern recognition in sentence completions and is more descriptive of salient patterns than explanatory. The stage descriptions include not only the *structure* of cognition, as in MHC and LAS, but also degrees of differentiation of the language used and shifting patterns of preoccupations in different stages, i.e. the *contents* of cognition. Robert Kegan's subject-object theory focuses the shifts in relationships between a self that is reconstructed in several stages on the one hand, and what this self can take as objects of awareness. At each new stage a reconstructed self gains more capacity for actively regulating elements of experience. The ego development theorists who have explored late ego development stages emphasise the roles of construct awareness (Cook-Greuter, 2010) and self-awareness/witnessing (Joiner & Josephs, 2007; O'Fallon et al., forthcoming; Murray, 2017) in forming the characteristics of the late stages.

Construct awareness refers to the awareness of the constructed nature of language, representations of experience and generally to people's meaning-making (Cook-Greuter, 2010). A person with a highly realized construct-awareness is aware that thoughts, judgments, narratives, feelings, images, etc. are products of a process of assigning meaning that depends on the person's conditioning through, for example, biographical experiences and collective constructions of meaning permeating the social environment one is embedded in.

---

[2] The concept is closely related to Ken Wilber's use of the term "vision-logic" in later works.

Self-awareness and ***self-witnessing*** are related concepts. The notion of self-awareness has been assigned different meanings in the literature. Here it refers to real-time awareness of internal processes, such as perceptions, emotional reactions, thoughts, judgments, desires, impulses, etc. (Jordan, 2001). A person with a highly developed self-awareness notices and can reflect on emerging thoughts, interpretations and feelings as they happen. Self-witnessing goes one step further and refers to a stable ability to witness upcoming internal events without being compelled to react and act in certain ways. Another way of putting it is that there is a fundamental acceptance of whatever transpires in the sense of not resisting the actuality of what happens (which does not imply that one doesn't take action when action is needed). The concept "witnessing" covers a broad range and can occur occasionally at rather early levels of ego development. A comprehensive and stabilized capacity for witnessing is intimately linked to the establishment of a more permanent self identification with the witnessing position. Mental and emotional processes are then perceived as events happening in the bodymind, but the self has a considerable freedom to make decisions about how to relate to those events.

Meta-awareness refers to awareness of awareness, i.e. a recognition that awareness as such can be differentiated from the contents of one's awareness field (Jordan, 2001; Kelly, 2015; Spira, 2017). Strong meta-awareness means a direct experience of the quality of "pure awareness", that there is a position for awareness that is not affected by the specific contents of awareness. Pure awareness is experienced to be unchanging, independent of time and space, empty but still a living presence without boundaries.

Spiritual awakening or ***enlightenment*** involves a profound shift in the nature of the sense of self, where the self is no longer identified as a separate self with a boundary to the environment and other people (Adyashanti, 2009; 2011; Culadasa et al., 2015; Frazier, 2012; Martin, 2012; Ullman & Reichenberg-Ullman, 2001; Young, 2016). The self is identified as a ***pure awareness self*** felt as boundaryless (ego dissolution), at one with everything, not separate. This can be associated with a very intense experience of well-being and sometimes an ecstatic sense of unity with everything. When thoughts and feelings occur there is no "I" they belong to. Spiritual awakening, at least in many cases, seems to be connected with (maybe also in some sense caused by) neurological changes in how the brain operates, e.g. deactivation of some brain subsystems and activation of other brain subsystems. This might explain why spiritual awakening can be a sudden event, rather than, as with ego development, the result of a slow process of gradual development.

Temporary "mystical experiences" can relatively reliably be induced by psychedelic substances (particularly LSD and psilocybin) under certain conditions (Barrett & Griffiths, 2018; Carhart-Harris et al, 2014; Griffiths et al., 2006; Liechti, 2017). A mystical experience typically includes the following qualities: A sense of boundaryless unity with something far greater than the individual self; a sense that everything is made up of one and the same consciousness; a very strong sense that one has encountered ultimate reality; an experience of sacredness; intense positive feelings of awe and well-being; and an experience of transcending boundedness in time and space (Barrett & Griffiths, 2018; Stace, 1960). Recent research using modern techniques for measuring brain activity under influence of psychedelic substances indicates that the experience of ego dissolution is connected with deactivation of the "default mode network", a network connecting different parts of the brain that plays a central role in continually constructing a narrative that allows the sustaining of a coherent sense of self (see e.g. Nour & Carhart-Harris, 2017). Studies have shown that various forms of meditation are associated with similar shifts in patterns of brain activity as induced by psychedelic drugs (see eg. Brewer et al. 2011). Temporary ego transcendence experiences are as such of little relevance here, however, the mode of experiencing the self and the world in mystical experiences is very similar to the experiences reported by persons who have attained persistent states of spiritual awakening, i.e. persons who experience themselves as enlightened. DiPerna (2014), referring to Brown (2006), uses the concept *vantage point* to denote the anchoring positioning of the self-sense in relation to the outside world and inner experiencing. Spiritual awakening is here understood as a durable shift in the self's vantage point, e.g. from being embedded in a separate ego, to identification as a pure awareness self.

In the practice-oriented literature on enlightenment there is often mention of the difference between the "gradual" and the "sudden" path to enlightenment, where the former emphasizes the need for disciplined training over a long time period as a prerequisite for spiritual awakening, while the latter refers to enlightenment as a sudden, spontaneous and radical shift. There are numerous accounts in the literature of individuals who had sudden enlightenment events with dramatic consequences, for example by Eckhart Tolle and Sat Shree. Some of these individuals needed several years of adaption to their now very different mode of experience before they could function in a stable way. The existence of such sudden shifts fits well with recent brain research that indicates that spiritual experiences are linked to deactivation and activation of certain networks in the brain.

Lasting shifts in the experience of self and world of the kind described in this section have documented beneficial effects that can be interpreted as development of maturity: a stable sense of well-being, liberation from embeddedness in emotions generated by past negative experiences, a strong decrease of self-referential thoughts (such as preoccupation with how one is perceived by others or a self-narrative as a victim) and a radical weakening of the need for ego defense mechanisms (see e.g. Martin, 2012).

Propositions

In the interest of keeping this reasonably brief, I have formulated a number of propositions about how the different aspects of development are related to each other. These propositions take the form of assertions, but they are just statements of my current beliefs, rather than truth claims. I invite you to critically review and discuss these propositions.

1. Late ***ego development*** stages are not defined by increasing ***cognitive complexity***.

The development of cognitive complexity is strongly correlated with the stages of ego development up to and including the stage Autonomous/Strategist (E8). Key properties of the ego development stages can be related to and explained by levels of cognitive complexity. However, this does not go for cognitive complexity in general, but specifically for complexity in cognition relating to the interpersonal (social) and intrapersonal (psychological) realms. Cognitive complexity in relation to the external non-human world is only weakly related to ego development. A person can be capable of highly complex reasoning about, for example, technical issues and still be scored at one of the conventional ego stages. The ego stages beyond Autonomous/Strategist are *not* generated by increasing complexity of cognitive operations, but by increasing ***construct awareness*** and, in the latest stage(-s), ***meta-awareness*** and an increasingly stable shift of the identification of the self sense to the pure awareness position.

2. ***Spiritual awakening*** is more or less independent of ***cognitive complexity***, ***complexity awareness*** and ***perspective awareness***.

Many individuals who are genuinely spiritually awakened have a weak perspective awareness and don't engage in highly complex mental operations, such as MHC's metasystematical, paradigmatical and crossparadigmatical levels of complexity. Weak perspective awareness can, for example, show up in the form of firm beliefs in the correctness of one's own particular belief system and discourse about the nature and patterns of spiritual awakening (enlightenment) and a corresponding categorical dismissal of alternative discourses.

3. People can have a very high level of ***cognitive complexity*** without having a strong ***perspective awareness***.

People can have the capacity of grasping and interrelating multiple systems of ideas without being able to reflect on the limitations of their own systems of meaning-making. However, metasystematical cognition (an ability to reason about and interrelate properties of systems) is a precondition for fully realized perspective awareness.

4. People can have a strong ***construct awareness*** without having a strong ***perspective awareness***.

This means being strongly aware of the constructed nature of thoughts, judgments and narratives, and therefore being able to take them as objects of a witnessing self that has a degree of freedom in deciding how to relate to the constructs, while at the same time *not* having the capacity to recognize the systemic nature of perspectives and actively using an awareness of properties of different perspectives for gaining insight and resolving complex tasks. Perspective awareness requires capacity for systems reasoning.

5. The phenomena referred to by the concepts ***spiritual awakening*** and ***construct awareness*** are related but not identical.

People can develop a high degree of construct awareness without having the profound direct experience of there being no self that is characteristic of genuine spiritual awakening.

6. The phenomena referred to by the concepts ***spiritual awakening*** and ***meta-awareness*** are also closely related but not identical.

People can have a firm experience of pure awareness (the quality of awareness apart from its changing contents) without experiencing the cessation of being a separate self.

Five Prototypical Late-stage Awareness Profiles

In this section I outline five different prototypical awareness profiles for individuals that could be argued to display late adult development patterns. The argument is that these profiles are examples of patterns that cannot comfortably be assigned to different stages in a unidimensional sequence of developmental stages. The table below gives an overview of the five cases.

Table 1: Five examples of different late-stage awareness profiles

	Cognitive complexity	**Perspective awareness**	**Construct awareness**	**Self-awareness**	**Pure awareness self**
Person A	Strong	Weak	Weak	Weak	Weak
Person B	Strong	Strong	Strong	Moderate	Weak
Person C	Weak	Weak	Strong	Weak	Moderate
Person D	Weak	Weak	Weak	Strong	Moderate
Person E	Weak	Weak	Strong	Moderate	Strong

A: Strong cognitive complexity. A is someone who is capable of perceiving and reasoning about complex systems, processes and how multiple dynamic systems interact and evolve. However, A's construct and perspective awareness are weak, A does not reflect on how the properties of A's own system of interpretation leads to selective perception, to foregrounding of some issues and backgrounding of others, and to a tendency to make use of a selection of concepts and causal principles when interpreting issues. Since A indeed has a strong capacity for perceiving and reasoning about complex interrelationships, A has reason to have confidence in A's own judgments. This confidence in combination with weak perspective awareness leads to a strong identification with A's perspective and, at best, a weak interest in alternative perspectives. At worst, A will actively dismiss the relevance of alternative perspectives without really trying to consider what might be valid insights offered.

A weak capacity for witnessing from a position outside identifications means that the sense of self is firmly embedded in a system of convictions.

B: Strong perspective awareness. B is a person whose meaning-making includes systematical and metasystematical reasoning. B is aware of dialectical interdependency and systemic causation, and therefore expects, inquires into and makes use of systemic conditions and processes. But B also directs the capability for grasping complex systems towards understanding the properties of perspectives. Not only perspectives "out there", but also B's own perspective. B is aware to some extent of how the properties of B's own perspective leads to selective attention and a pattern of foregrounding and backgrounding that follows from the particular patterns of the discourse system used to form the perspective.

B has, in a sense, a certain level of construct awareness. However, this applies mostly to being able to recognize that meaning-making *systems* are constructed. B has not developed a keen familiarity with the pure awareness position and is therefore also not identified as a witness self, but rather as a dynamic, complex self system with views and values, even though these are held with a great deal of lightness and flexibility.

C: Strong construct awareness. C is keenly aware that our concepts, images, narratives and even feelings and desires are constructed. C recognizes that the meaning assigned to mental representations is highly conditioned by both socially constructed meaning, and accumulated meaning-making patterns throughout a person's biography. This construct awareness has loosened up C's attachments to convictions and opened up space for the emergence of a witness self.

However, C's cognitive world is made up of mental representations on the concrete, abstract and formal MHC levels. There is little consideration of systemic connections, processes and structures. C does not have the cognitive skills required for roles that include managing complex tasks with a long time frame and overviewing and coordinating complex systems.

C is also not someone who has developed a keen interest in turning attention inwards, towards the details of the continuous stream of thoughts, emotions, desires and impulses generated in C's bodymind. C is therefore not very mindful in taking responsibility for C's own reactivity in social situations.

D: Strong self-awareness. D has a keen ability to notice internal processes, such as generation of emotions, evaluations, thought threads, interpretations, reactive impulses, desires, etc. This has lead to a certain degree of freedom in relation to those processes, and hence the beginning of a witness self. However, D has not developed the more complex forms of cognition, does not expect and operate with systems cognition and is not able to reflect on and make use of properties of different perspectives. D is not able to take own patterns of meaning-making, the systemic properties of D's perspective, as objects for reflection, and is therefore subject to them.

E: Pure awareness self. E has gone through a process of shifting what the self-sense is identified as, from identification with a separate self made up of convictions about the self and the world to an identification as pure awareness. This means that E doesn't have any substantial need for defense mechanisms that protect the coherence of the ego, and therefore no need to manipulate other people into supporting own ego needs.

E is well aware of the constructed nature of thoughts, narratives and emotions. However, when E has to engage in problem-solving or talk with other people about complex issues, E still has to use a perspective made up of concepts and convictions. This perspective is not essential to E's sense of identity, but since E does not have the capacity to recognize and reflect on the systemic properties of perspectives, E will easily fall into a strong belief in the correctness of E's own views.

E's identification as pure awareness does not mean that E has a keen mindful contact with the stream of thoughts, impulses and emotions that the body and the sum of earlier conditionings give rise to. E does also not have a well honed skill in detecting what other people feel and think, and sometimes handles social relations in unskillful ways.

The five prototypical profiles outlined above are intended to provide food for reflection rather than making validity claims. Is it reasonable to assume that such combinations as in these five examples might exist? Even if the ego development frameworks of Cook-Greuter and O'Fallon would prove to describe the most common patterns of late ego development, are there significant variations that cannot easily be assimilated into the models?

Empirical Studies

I have not been able to find more than a few empirical investigations into the correlation of different aspects of adult development, such as cognitive complexity, ego development and spiritual awakening. However, the few studies that have been made are intriguing in terms of the basic questions asked in this paper. Here are two examples:

Glenn Mehltretter (1995) studied 25 subjects by having them fill out the Washington University Sentence Completion Test and scoring interviews using Jaques' Complexity of Mental Processing model. All but two of the subjects were scored at the Self-aware and Conscientious ego development stages. Of the 11 subjects who were scored at the Conscientious stage, the CMP score varied from 2,5 to 6.75, indicating a very wide spread of cognitive complexity among people who scored at the same ego development stage.

Jeffery Martin (2010) recruited 36 individuals who self-reported a "persistent non-symbolic experience", i.e. being spiritually awakened. He let them fill out the Mysticism Scale form and the Washington University Sentence Completion Test. All participants scored high on the Mysticism Scale, confirming their self-assessment as fulfilling a range of criteria for being spiritually awakened. Their ego development scores were spread out over six ego development stages, from Self-aware to Unitive (according to Cook-Greuter's elaboration of Loevinger's framework), with 12 participants at Self-aware and Conscientious, 11 at Individualist and 13 at Autonomous, Construct-aware and Unitive, thus indicating that ego development and spiritual awakening are not correlated.

Both studies are very limited in terms of number of participants and in both cases there are methodological limitations, but they certainly indicate that there are reasons for doubting that there is a strong correlation between the three constructs cognitive complexity, ego development (in the Loevinger-based tradition) and spiritual awakening.

Conclusion

The purpose of this text is to point to a couple of questions about the validity of certain assumptions that seem to be built into some of the theoretical frameworks used to describe and explain adult development, here with particular focus on the late/high/mature forms. There were two more concrete reasons that triggered me to write these pages. One was the recurring assertion among the advocates of hierarchical complexity frameworks (MHC and LAS) that cognitive complexity is the key variable that can explain many empirical patterns of development among adults. The other was Terri O'Fallon's claims that her StAGES model can both describe and explain ego development from childhood to transpersonal forms in terms of a linear sequence of stages formed by the combination of a small number of variables. I want to invite scholars in the field to critically inquire into both views. I believe that the hierarchical complexity frameworks exclude from consideration aspects of adult development that are essential to understand the nature of late forms of development, notably self-witnessing and the transcendence of the sense of a separate self described in the literature on spiritual awakening and mystical experiences. I am also concerned that the assumption that later forms of development can be accurately represented through frameworks that describe a linear sequence of ego development stages might obscure the variability of patterns. It seems warranted to specifically inquire into the variability of developmental patterns, using a number of different analytical constructs. For some of these, quite well researched measurement instruments already exist, which could be used in combination in empirical studies in order to test correlations. However, I also believe that it would be productive to use qualitative methods, such as semi-structured interviews and 360 degree assessments, that allow for probing a broad range of indicators of different aspects of late/mature forms of adult development.

The propositions formulated in the second main section of this paper are meant as invitations to dialogues, discussions, or (though less appealing) debates about the strengths and limitations of different theoretical frameworks, including consideration of the epistemological assumptions behind the orientation in our field regarding theory construction. There is still, in my opinion, too much monological rationality and too little practice of perspective awareness in the field of adult development. Creators of theoretical frameworks often have, not surprisingly, a nomothetical bent, i.e. they strive to develop an elegant framework that explains a lot with one basic principle. The potential weakness of nomothetical scholarship is the striving for theoretical simplicity, which tends to marginalize consideration of variability. I think we also need idiographical approaches to theory-building, approaches that aim at capturing and explaining variation by constructing theoretical frameworks that flexibly can combine different variables. At the very least, I do hope that scholars will stop including tables in their articles and books where they correlate higher levels of hierarchical complexity with the late ego development stages.

Editor's Invitation

Integral Review invites you to consider submitting a response to expand the dialogue begun here. What reflections, clarifications, inquiries etc. emerge for you from reading Jordan's presentation of these distinctions, propositions and considerations? We would like to gather such responses to publish in the next issue of Integral Review.

The Construct-Aware Stage of Ego Development and its Relationship to the Fool Archetype

Susanne Cook-Greuter[1]

This brief essay is based on a keynote and workshop held at the 3rd Integral Theory Conference in Siófok, Hungary, May 2018. It addresses the fine art of Foo-Ling, the use of laughter as a tool to lighten up our own lives and the lives of those around us. While fools and jesters can come from any stage, it is a late-stage discovery to recognize the poison of taking ourselves too seriously and its antidote: light-heartedness and delight. Let's face it, we Integralists take ourselves and our mandate to raise collective consciousness very seriously. That is why we exchange ideas and work with each other. As integralists we have much important knowledge to share. And while that is as it should be, I am here to remind us of the fool in all of us and to engage in our work with a deeper level of awareness.

Ego development theory proposes that it is a characteristic of maturity to discover that not knowing is the highest form of knowing. Foo-ling is about the capacity to recognize the folly of trying to explain and map everything. It is about truly seeing how thoroughly we tend to confuse our maps and theories with the territory.

Some of you may bristle at this notion of being a fool especially if you cherish your identification as an Integralist or expert in constructive developmental theory. The question Horace asked in ancient Rome: Who is not a fool?[2] Moreover, Shakespeare's fool Feste in act III of *Twelfth Night* had this to say "Foolery, sir, does walk about the orb like the sun, it shines everywhere."[3] Finally, we quip: "Anyone who does not wish to see a fool, should smash his mirror."

---

[1] **Susanne R. Cook-Greuter** is an independent scholar who is recognized for her ground-breaking work in ego development theory and the function of language in meaning making. She has a doctorate in human development and psychology from Harvard. She is a founding member (2000) and an elder of Ken Wilber's Integral Institute and the integral community. She sees herself as a benevolent skeptic of all the certainties and beliefs espoused in the field of vertical development and transformational and approaches. At the same time, she remains fascinated by the very joys and challenges all humans face on the pilgrimage through life. From 2018 on she will delegate world-wide engagements to disseminate developmental insights and in training in tailored coaching to a group of highly committed colleagues. Instead, she will be focusing on writing the definite book on ego development and continue to do research with and about the MAP instrument.

SOME RIGHTS RESERVED

You see, you and I are in the best of company. We are all fools when we so avidly strive to gain greater insight to master our lives, reach nirvana and hope to leave traces of our greatness. As a group we tend to believe that if only everyone else could collaborate and see the world through our color-tinted glasses, then we could be saved from our self-induced global calamity both as individuals and as a species and create the longed-for better world.

I am an old fool. I have known that I can be fooled for a long time. An early rude awakening was to discover that the much-feared Santa Claus turned out to be a neighbor dressed up in Santa gear. The longer we have lived and the more we think we understand about existence, the more we need reminding of the Buddhist teaching that says: “Understanding is the ultimate illusion.”

I propose that there is a relationship between the capacity to see through the function and games of the ego and the archetype of the fool. Both show an increasing affinity for mirth and laughter. Both tend to point to all that is pretentious, self-important or takes itself too seriously.

Since time immemorial, all cultures, groups and individuals have told stories about where they come from, and who they are in relation to nature and the universe. They have explanations about why they exist and where they are headed in life and after death. From myths to grand theories of everything, storytelling seems to be a universal human characteristic.

Based on my observations, the Construct-Aware stage in ego development theory is the first in which some people begin to explore our astounding world-wide impulse to explain everything under the sun and the concomitant capacity to fool ourselves about what it means to know.[4] It’s liberating to be able to take life more lightly and to laugh at ego’s sincere and relentless efforts to cement its illusive supremacy.

What is Ego?

First, what do I mean by ego?[5] As I define it in ego development theory, ego underlies the universal drive to explain everything and make us feel safe, important, and to belong. Ego represents the striving of human beings to understand themselves and the world they live in. It is the tireless organizer, interpreter, and synthesizer of experience. Its task is to turn experience into a coherent narrative about the world. How does it do that? It does so by telling a culturally influenced story about who we are, why we are here and for what purpose.

Overall, the ego labors mightily to create and maintain meaning and vigorously defends against dissonant information and its deep, unspeakable sense of helplessness. Indeed, when we are not able to tell a good story about ourselves and our tribe, we feel anxiety and despair. Ego is invested in the denial of death, and in upholding the illusion of our immortality. Therefore, facing and embracing our finitude is part of late-stage realization.[6]

---

[4] There are several adult measurement systems that equate being able to give complex explanations with human higher human performance and maturity primarily based on hierarchical complexity and skill theory.

[5] In several spiritual traditions the ego is framed as the enemy. Indeed, seekers are admonished to kill the ego. But who else but the ego itself would strive to get beyond itself?

It is at the Construct-Aware stage that one becomes aware of ego's narrative function and its cleverness at fooling us into thinking we can know and understand. Few people begin to question the function of ego and our need for myths, stories, and theorizing. Even rarer among ordinary adults, some individuals learn to look kindly at ego's tireless striving for security and preeminence while seeing through its hopeless efforts.

Construct-Aware folks are the first who potentially realize the illusion of "knowing" and the futility of trying to make ever better maps of reality. Other names for the Construct-Aware stage are Magician, Alchemist, Fool, and Jester. It is these latter two aspects of the Construct-Aware stage 5/6, that I will explore further here.

The Role of Language and Culture

Overall, human development as I describe it, moves from the newborn's unconscious union with mother to a conscious union with everyone and everything. As we grow up we construct meaning by learning the vocabulary, memes, grammar and the scripts available to us from our languages and cultures. Languages divide lived experience into separate objects with distinct boundaries and evaluative attributes. We are so totally immersed in a sea of language that we hardly notice the way it lures us into a false sense of knowledge and how it molds us into very particular notions of what is real and important.[7]

The idea of a separate self in Western cultures is just one result of this phenomenon. It is ironic that all of us have to communicate via symbols. Ironic also that concepts such as "purpose" and "soul" as well as "ego" are symbolic abstractions that do not exist outside of language and our agreed upon definitions. Yet we treat them almost always as if they were palpable, real things. We could choose to remain silent in the face of this paradox or to speak out and laugh at our dilemma while remaining conscious of the trap of speaking.

In this context, I will mainly address aspects of the penultimate stage in ego development theory, the Construct-Aware stage 5/6. The stage has several expressions: The *cognitively-focused* Construct-Aware and the more *meaning-focused* Ego-Aware. A third, more *action-oriented* form pertains to folks who bravely hold up the mirror to society and intervene in real time to debunk all forms of accepted dogma, non-sense, and pretense. The third form is the closest to the fool archetype.

---

[6] In the we-space context, the ego can turn multiple "I"s into a "we" with much the same mandate: To defend against recognizing that we are mortals and live in an unpredictable cataclysmic universe. No one knows what the future will bring. Whether I or we, ego's noble task remains the same: to make us feel secure, special, and immortal.

[7] While there has been an ongoing argument whether Nature or nurture is more shaping our thoughts, the Ted talk below gives a succinct argument of differences not explainable by nature only.
Lera Boroditsky, 2017, On how language shapes the way we think
https://www.youtube.com/watch?v=RKK7wGAYP6k

The job of wise men and jesters has been to expose the blind spots of society and to unmask any emperor with new clothes since time immemorial. They often do so at the risk of their own lives as their message is rarely welcome. Gifted fools, however, can come from any stage, and yet it is at stage 5/6, that one first fully realizes there is nothing to gain or lose by pretending to know. We are just here, now, alive, on this tiny blue pebble hurtling through a vast mysterious universe. Existence cannot be explained without recourse to storytelling.

The first, the Construct-aware form of stage 5/6 understands the human need to create ever more comprehensive explanations of reality despite knowing that lived experience cannot be captured in words.

We think we are taking hold of reality when we concoct a plausible theory about it. Far from it. Our lived experience is always dynamic, moment to moment, and seamless comprised of myriad fleeting sensory impressions, feelings, and thoughts. The maps of reality we construct can never depict the undivided whole, the actual lived territory. They are, at best, temporary, and useful approximations that serve us as guidelines.

Moreover, we trust science and technology as well as highly developed human minds that we can and will eventually be able to explain the cosmos. Constructive adult development theory buys into this conception by asserting that meaning is made and that we can explain what it takes to become a mature and highly evolved human being.
